Vol. XV. NEW YORK, JULY 13, 1898. No. 1.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4081 Cortlandt.

SUBSCRIPTION RATES:

United States,	$2.50
In Clubs of Five or More,	2.00
Foreign Countries,	4.50
Single Copies,	10 cents

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

A Novel Method of Submarine Cable Laying.

In view of our present hostilities with Spain, and at a time when the establishment of speedy communication between a fleet or army and the home government is of the most vital importance, a statement recently made by two well-known Englishmen at a meeting of the Royal United Service Institution in England is worthy of attention. These two gentlemen, whose names are Lieutenants William C. Crutchley and C. Scott Snell, and who are said to be experts in the science of military signaling, suggest that instead of relying upon the cables that may already be in existence for commercial purposes a naval commander might lay a number of special cables of his own. With the ordinary cable-laying apparatus now in use this would be an extremely difficult matter to accomplish expeditiously, and on this account Messrs. Crutchley and Snell are said to have devised a form of apparatus which may readily be fitted to any warship and will enable a commander to accomplish the desired result. The *Daily News* of London alludes to the device and describes the method of laying as follows:

"These inventors have devised apparatus by means of which a submarine cable can safely be laid at any rate of speed within the compass of the fastest cruiser. This is very far in excess of anything which has hitherto been accomplished, but there is little doubt that the plan is feasible. The apparatus is capable of being fitted to a warship or a properly equipped telegraph-ship, or, as an alternative, there is a temporary arrangement which is capable of being adapted to any vessel at very short notice.

"A pulley at the stern of the ship ejects the cable overboard, and is driven by a motor. Beyond this stern pulley is a wide drum, over which the cable passes on its way from the hold. In conjunction with the drum is maintained 2,000 feet of cable under a constant tension.

"The idea of a cable running out at twenty knots is rather startling, but experts are of opinion that this could be accomplished. The inventors have devised an apparatus for holding it in hand and completely stowing 2,000 cubic feet of cable, called the 'cable accumulator' (a small unit system of carrying the cable, which consists in placing the cable on board in drums of forty knots' capacity, and arranging them in columns, from which the cable is drawn off alternatively), an 'automatic traveler' to receive the cable as it leaves the drum, and finally a controlling system whereby an officer located in a chartroom keeps the attendant at the ejecting engine aware of the needed paying-out speed."

As will readily be seen, Messrs. Crutchley and Snell claim that by means of the apparatus they have invented, and in the manner in which the cable is coiled on board the vessel, it can be laid while the ship is running at twenty knots an hour, whereas heretofore under the most favorable conditions eight and one-half knots has been considered quick laying, it frequently being necessary even to reduce the speed to four knots. Another important claim made by these inventors is that a ship might place itself over a cable which lay in moderately deep water and transmit messages without making actual metallic contact with it, by means of induced currents. In support of this theory it was pointed out that messages have beeen transmitted and received by means of induced currents between a moving train and wires running along the track. In this case, however, the roof of the baggage car in which the receiving and transmitting instruments were located, and to which the receiver was connected, was of tin and practically insulated, and moreover, the distance between the car and wires was comparatively short. Whether intelligible signals could be transmitted by means of induced currents through any considerable depth of sea water, as is claimed, would seem rather problematical, and any experiment made along this line will unquestionably be watched with interest by the scientific world.

* * *

The War Tax on Telegraphic Messages.

From all accounts there would seem to be considerable uncertainty as to who should affix a tax stamp upon telegraphic messages. The Commissioner of Internal Revenue is said to be receiving scores of telegrams and letters from merchants, manufacturers and boards of trade, as well as from Senators and Representatives, asking his construction of the War Revenue Act of 1898 relating to this affixing of a stamp upon telegrams. The law apparently in no way specifies who shall affix the stamp, whether the sender of the message or the company, but simply imposes the tax of one cent upon each message and prescribes that "no telegraph company or its agent shall transmit to any person any dispatch or message without an adhesive stamp denoting the tax imposed by this act being affixed to a copy thereof, or having the same stamped thereon, and in default thereof shall incur a penalty of $10." In almost every case where a commodity has been taxed, and especially is this so in the case of proprietary articles, the consumer has been obliged to bear the whole burden of the tax, and in some cases even more than the tax, for where an article has called for a stamp of a denomination of less than a cent the consumer has been charged an extra cent. Undoubtedly the consumer should bear his share of the tax, but it scarcely seems just that the whole

tax, and in some cases even more than the whole tax, should be thrust upon him. In the case of telegraphic messages, where the tax is but one cent, why not have the sender affix a stamp when the message consists of ten words and the company agree to pay the tax when the message consists of over ten words. This arrangement would unquestionably favor the telegraph companies, but at the same time the patrons of the various telegraph companies would not feel that they were bearing the whole burden of the war tax on telegrams.

The Omaha Meeting of the American Institute of Electrical Engineers. The Fifteenth General Meeting of the American Institute of Electrical Engineers, recently held in Omaha, Neb., was probably one of the most successful gatherings ever held by that body in spite of the fact that but few Eastern members were present. The papers that were presented were with but few exceptions of a practical nature, which is certainly to be commended, as heretofore many subjects have been discussed at meetings of the Institute that were not, as a member once aptly expressed it, "within five miles of earth." Probably the most important subject brought to the attention of the members present was the preliminary report of the Committee on Standardization. This report, which was carefully compiled by seven electrical engineers of high standing, familiar with every branch of the electrical industry, has for its aim not only the standardization of the sizes of apparatus, but also includes all the definitions and terms usually met with in electrical specifications, as well as suggestions for standard methods of making and recording tests. The first subject touched upon in the report is that of "efficiency." After defining the term and stating how the electric power should be measured for various types of machines and on transmission lines, the question of the rise of temperature is taken up and rules laid down as to how and where such temperature should be measured. Insulation and dielectric strength are next touched upon, and rules given as to where all insulation resistance tests should be made. The regulation of apparatus is fully discussed, and rules laid down as to how it should be measured. The variation and pulsation, rating and classification of voltages and frequencies are all carefully dealt with. The report ends with the recommendation of an already fairly well standardized notation. Although the recommendations regarding the standardization of apparatus were quite fully discussed at the Omaha meeting, no definite action was taken toward its adoption. It would be well were some such uniform standard generally accepted internationally, and it was possibly with some such object in view that definite action was deferred for the time being.

Average Earnings of Street Railways in 1897. The 1898 edition of the *Street Railway Journal's* financial supplement, which has just appeared, contains a careful comparison of the gross earnings of the principal American street railway properties for 1896 and 1897 which we think should prove of interest to our readers as furnishing a means of judging to some extent of the prosperity of the country. During times of unusual business depression, or in what is familiarly known as "hard times," the gross earnings of street railway companies are as a rule affected, and a careful comparison of the gross earnings of a number of street railway companies extending over a period of several years will usually afford an excellent thermometer whereby to judge of the financial condition of the country. According to the figures in the "Street Railway Red Book," of 175 American street railway properties the Union Traction system of Philadelphia leads in gross earnings with receipts aggregating slightly less than ten and a half millions, or with a gain of only $270,620 in gross receipts over 1896, or 2.65 per cent. In the group in which the Union Traction system is to be found, numbering twenty-six systems in all, i.e., those properties earning one million dollars or more annually, there was but an average gain of 2.2 per cent. in 1897 over 1896. In the second group, comprising nineteen roads earning from $500,000 to $1,000,000, there was a decrease in gross earnings of 0.11 per cent. in 1897. In a third group, comprising 46 properties earning from $100,000 to $500,000, the gross receipts increased as a whole 1.87 per cent. in 1897 over 1896. In the smaller systems the variation in gross receipts between 1896 and 1897 was very slight. The average in gross earnings of the whole 175 properties shows an increase of but 1.9 per cent. in 1897 as compared with 1896. It is interesting and rather surprising to note that the average increase in gross earnings of all these properties was less between 1896 and 1897 than between 1895 and 1896. This falling off in average gross earnings in 1897 may partially be accounted for in the growing use of the bicycle for business purposes and to the slow recovery of industrial activity among the masses of the people. Under the present existing conditions in this country, it would not be surprising if the average gross earnings for 1898 should be even less than for 1897.

Under the Searchlight.

Notes and Comments on Various Topics.

The Proposed Reduction in G. E. Stock.

The Boston *News Bureau* of July 6 says:

The General Electric preferred stock committee has considered the proposal of the directors of the General Electric Company to reduce the stocks of the company, both preferred and common, 40 per cent. to $60 par value, and a majority of the committee has decided not to recommend this proposition to the preferred stockholders. Mr. Carr, the minority member of the committee, representing the Ames estate interest in the preferred stock, was in favor of accepting the proposition. The Ames stock, therefore, not having been deposited with the committee, will probably be voted at the meeting of the General Electric stockholders in favor of the proposition to reduce the stocks of the company to $60 par value. Messrs. Livermore and Atkins, the majority of the preferred stock committee, will shortly issue a circular outlining their proposed action in regard to the preferred stock. Mr. Carr will withdraw from the committee.

As we stated in an editorial in our June 22 issue, there would seem to be no valid reason why the preferred stockholders should be obliged to bear practically the whole burden in the proposed reorganization of the General Electric Company, which has been brought about through the efforts of ELECTRICITY. That a reorganization is absolutely necessary we have claimed and proved for several years, but it is likewise plain to be seen that if the accumulated dividends, now amounting to $1,488,200, on the preferred stock, are paid it will wipe out all the earnings of the General Electric Company for this year, and consequently no dividends need be looked for next year, and possibly for several years to come. No account has been taken of these back dividends, and in the annual reports issued by the General Electric Company the accumulated dividends have systematically been omitted from the list of liabilities, which, as we have all along claimed, is decidedly wrong. ELECTRICITY has pointed out to the directors time and again that these accumulated dividends were a liability which would some time have to be met. Were we preferred stockholders, we should unhesitatingly side with the majority of the committee and oppose the reduction of the preferred stock in the manner proposed.

* * *

IN a scrimmage between employees of the Monmouth Traction Company and those of the Pennsylvania Railroad Company at Bordentown, N. J., on the 8th inst., about the raising of a pole on disputed ground, an incident occurred that will probably be utilized by some of our realistic playwriters as an effective scene in an East Side drama. The particulars as we find them in the Pennsylvania *Inquirer* are as follows: "When the trolley men prepared to raise the pole Mayor James S. Gilbert appeared with Marshal H. N. Jobes and twenty-five officers sworn in by him and gave warning that any one interfering in the work would be arrested. The street was crowded with people. The railroad company also had a big force on the scene. The raising of the pole alongside the hole was the signal for both forces to come together. Railroad men jumped into the hole and were yanked out by the trolley men. Supervisor F. J. Potter and his assistants, Richard Silvers, Joseph Venable, Frank Eldridge, James Lewis and Edward Ford, all Pennsylvania Railroad employees, were arrested and taken to the City Hall. Later they were released on an order from Justice Garrison, of Camden. In the meantime the trolley men had conquered and the pole was planted. The railroad men then undertook to saw it down, and in the scrimmage Marshal Jobes and James Lewis were slightly cut by the saw. Then a Monmouth Traction man was seized with a happy thought and climbed to the top of the pole with an American flag. He remained on his lofty perch for nearly three hours and dared those beneath to cut the pole down, but no one attempted to do it. Late in the afternoon, however, the pole was ordered removed by Councilman Thomas Gash, chairman of the Street Committee. It was moved a distance of several feet to another property, the committee claiming after an examination of the ordinance and a measurement of the street that the pole was erected in the wrong place. It now stands in its rightful position."

WE are in receipt of the following notice:

TWENTIETH TRIENNIAL EXHIBITION.

Office of the Executive Committee, Mechanics Building.

Boston, May 27, 1898.

It is well known that the General Electric Company do not place exhibits with local expositions. Assured of the high character of our October exhibition, they will present a large working exhibit with us.

MASSACHUSETTS CHARITABLE MECHANIC ASSOCIATION.

Possibly the "working exhibit" referred to will show the visitors at this exhibition the General Electric Company's method of manufacturing stocks and bonds at will.

* * *

Peculiar Antics of a Lightning Bolt.

During a severe thunderstorm on July 5 the home of a certain gentleman in California was struck by lightning. The bolt struck a big locust tree in the yard, jumped from that to the peak of the house and burned or melted some nails in the wood. From there it went down the attic window post, which was splintered, and went through the plastering in five small holes. It looked as though the holes were made by a gun. It set the lace curtains on fire and partly burned a feather bed. The bolt seemed to part here, part going out front and part going back. The part going front damaged the shutters, ripped off the plastering, followed some nails over the door-head and melted the wire on a screen door and went into the ground under the front steps. The part that went the back way doubled again before it entered the ground, one part taking one side, tearing out a window frame, following a tin valley down a doorway, ripping off plastering and laths and then into the ground. The part that took the other side ran along a partition, ripping off laths and plastering, down the back stairway and through a tin safe or cupboard. In the cupboard were knives and forks. These were melted and stuck where they came in contact with each other. From the cupboard it went through the corner of the house, tearing off plastering and weather boarding and ripping open the corner posts.

LACHINE RAPIDS PLANT AND THE COST OF PRODUCING POWER FOR GENERATING ELECTRICITY THEREFROM.*

BY W. M'LEA WALBANK.
Montreal, Can.

In order to allow of a fair comparison with other plants, of the cost of producing power for generating electricity from the Lachine Rapids plant, the writer considers it desirable to give you a brief outline of the hydraulic as well as the electrical equipment of our works.

The world renowned Lachine Rapids, as you are all doubtless aware, is situated on the St. Lawrence River, a short distance from the city of Montreal.

The idea of converting the wasted energies of these turbulent waters and harnessing them for the use and convenience of man was not new. As far back as 1866 a company was formed whose object was to erect dams and construct large hydraulic works about a mile lower down the river than the site of the present power house, their object being to induce factories to establish their works at the rapids, for at that date the possibilities of electric transmission had not been demonstrated. The scheme, however, never materialized, and since that date various projects have from time to time been talked of, but never matured.

In the fall of 1895 the Lachine Rapids Hydraulic & Land Company, Ltd., commenced its operations. The directors commenced work only after having fully satisfied themselves upon the difficulties to be encountered and overcome, and carefully studying the question of back water, frazil and anchor ice, and went in with a determination to succeed.

The company was honestly formed, without "ground floors" or "sub-cellars," with a bona fide capital in which every share represents one hundred dollars ($100) cash. This, the writer considers, has direct bearing on the cost of producing electricity, because a company handicapped by what is called watered stock, or exorbitant promoter salaries, has to pay interest on money it never had the use of.

Having therefore formed a company on a solid and firm financial basis, the property fronting on the Lachine Rapids, and controlling the water power privileges, was secured, and operations for the development of the water power commenced.

HYDRAULIC DEVELOPMENT.

The hydraulic plant consists of a main dam and power house, one thousand feet long, and a wing dam and guard pier five thousand feet long, forming a head race or basin with an average depth of twelve feet at low water.

To secure this it was necessary to divert the waters of the St. Lawrence and lay bare the bed of the river for a distance of over a mile and remove over 400,000 cubic yards of rock.

The main dam, which is constructed of a series of isolated cut stone piers, with head gates and stop logs, furnishes in all thirty-six (36) flumes and three (3) waste weirs, at the same time forming foundations for the power house and turbine sheds.

The total development will, when completed, consist of seventy-two (72) vertical turbine wheels and twelve (12) generators, the wheels connected in series of six, by gearing, to a horizontal shaft, at the end of which a generator is directly connected. The completed power house will contain twelve (12) such sets.

Of the total installation forty-eight (48) wheels are already in place, and the power house, head race, tail race and dams are completed.

ELECTRICAL EQUIPMENT.

Each dynamo house will contain four (4) three-phase General Electric alternators, wound for 4,400 volts at full load, and two direct-current exciters at 120 volts. There will be in the total installation three such dynamo houses, containing in all twelve dynamos and six exciters, each exciter being capable of exciting four machines. Each dynamo house will have its own switchboard, of blue Vermont marble, of the very latest design, so arranged that each circuit may be operated from the switchboard of either power house. The floors are of slate and the building of solid brick. The current is generated at 4,400 volts, avoiding the use of step-up transformers, is transmitted on iron poles over bare copper wire to the city of Montreal, a distance of about five miles, to the sub-stations, where the pressure will be lowered to 2,300 volts, and by means of sub-station switchboards sub-divided into the desired units and distributed partly through underground conduits, and partly by overhead construction, throughout the city of Montreal and its suburbs, where we find a population of over 300,000 people offering a market for light and power.

Of the total equipment one-third is already installed.

TOTAL POWER.

The wheels were tested at the Holyoke testing flume on April 16 and 17, 1897, and developed at full gate as follows:

With a speed of 76¼ revolutions, discharging 235.33 cubic feet of water per second and developing 300.84 horse power, showing an efficiency of 81.32 per cent., which would make the total possible output of our power house about 16,000 kilowatts.

COST.

Perhaps the greatest obstacle to a fair comparison of electric current produced by water power, as against the same current produced by steam, is the first cost. In the former case, especially if a large water power is to be developed, the expense of the whole installation, such as dams, head and tail races, etc., has usually been made at the commencement, while perhaps only a fraction of the power thus obtainable is at once used, therefore throwing a very much larger capital cost per unit than with a steam plant, which need only install the power necessary for immediate demand and continue increasing or adding thereto as the demand therefor offers.

In our own case you will notice it was necessary for us to spend about one million dollars ($1,000,000) in hydraulic development. This million dollars is able to furnish us over twenty thousand (20,000) horse power, whereas it will be some time before we will be able to convince the public of the advantages to be derived from the use of electricity, which is no easy task, as anyone familiar with the subject will bear out.

The 5,000 horse power from a commercial point of view will have, for the present at least, to be charged with all the expense of the hydraulic development of over 20,000 horse power.

In estimating the cost of producing power from the Lachine Rapids, the writer does not take into consideration the cost of distributing power, for this would be the same in either case, whether the prime mover was a water wheel or a steam engine. He will therefore confine himself to the cost of developing water power and delivering that power on the bus-bar at the sub-station, exclusive of the generator. He will add the cost of transmission line from the source of power to the sub-station in the city, because this is directly attributable to water power plants, as it would not be necessary in the case of a steam plant, unless it were for transmitting power from a coal mine to a city, or following the practice laid down by the Brooklyn Edison Company, in locating their power house at a point convenient for obtaining coal and water at reduced prices, using high-tension transmission, and converting by rotary converters at various sub-stations.

There will also be included the step-down transformers to bring the pressure equal to that required for local distribution, namely, in the neighborhood of 2,000 volts.

He will also charge the water power with the drop or loss in power from the rapids to the sub-station.

The writer therefore considers, in justice to the Lachine Rapids plant, it would be necessary to give, first, the cost per kilowatt per year for the portion of the plant at present installed and connected to generators ready for operation, and second, what the cost will be per kilowatt per year when the whole water power development is in operation.

First—The total cost of water rights, dams, hydraulic machinery, power house, transmission line, step-down transformers, etc., is $957,200.

Power developed, 4,000 kilowatts at the generator. Allowing 10 per cent. loss, there will be delivered at the sub-station bus-bar 3,600 kilowatts, which is equivalent to $263.83 per kilowatt, capital cost.

This, at 6 per cent., would be equivalent to	$15.95 ꝑ KW.
Depreciation of $300,000, which will more than cover the cost of that portion of the plant subject to depreciation, rated at 5 per cent. and spread over 3,600 kilowatts, would be equivalent to	4.17 ꝑ KW.
Operating expenses, including labor, repairs, insurance, amounts to $10,275 per annum, which, divided into 3,600 kilowatts, is equivalent to	2.85 ꝑ KW.
Making a total cost per kilowatt on a twenty-four hour day basis, per year	$22.97 ꝑ KW.

Second—The total cost per kilowatt with the whole water power plant in operation.

Before giving these figures the writer would like to explain that the figures herewith quoted are reliable for the cost of the completed plant, inasmuch as the same is at present under contract with reputable firms, the Lachine Rapids Hydraulic & Land Company having a limited time in which to order the works completed.

The total capital cost with seventy-two wheels installed will be $1,113,273.

Power developed after deducting all losses will be 13,500 kilowatts at the sub-station bus-bar, equivalent to $82.46 per horse power capital cost, which, at 6 per cent., represents (per annum)	$4.95 ꝑ KW.
Depreciation per kilowatt will equal	1.68 ꝑ KW.
Operating expenses, including labor, repairs, oil and waste and insurance, if taken upon the same basis as already existing, will amount to $20,453, equivalent to	1.51 ꝑ KW.
Making a total for a twenty-four hour run per annum of	$8.14 ꝑ KW.

It will be noticed that the operating expenses, as well as the depreciation per kilowatt, in the latter case is very much reduced, and it is a remarkable feature how constant our operating expenses are, even at present, being practically the same with full load as with no load.

In connection with these figures it might be stated that coal used in Montreal and vicinity is what is known as Nova Scotian coal and costs $3.50 per ton for run of mine.

The writer would also draw your attention to the fact that the capital cost cited in each of the foregoing cases includes money paid for real estate, of which the company owns over some eight million feet, fronting on the rapids, intended at some future date to form the site of a suburban town, and which it is hoped and expected will return the money expended in developing the water power above referred to.

CONCLUSIONS.

From the foregoing the writer trusts that he has shown that where reliable water power can be ob-

* Paper read before the National Electric Light Association at its Twenty-first Convention, Chicago, Ill., June 7, 8 and 9, 1898.

tained within reasonable distance from power centers it can be made to produce cheap electric current, to say nothing of the great advantages the city must derive therefrom, not only commercially, but viewed from a sanitary standpoint as well, as the use of electric power thus generated is the best smoke consumer yet invented.

TRANSFORMER ECONOMY.

BY PROF. WINDER ELWELL GOLDSBOROUGH,

Purdue University, Lafayette, Indiana.

A great deal has been said and written about the static transformer of alternating currents, and yet we are only just beginning to understand this much discussed piece of apparatus. The manufacturers have made it and experimented with it, the theorists have experimented with it and disputed over it, the underwriters have disputed over it and endured it, and the central station men have endured it and made use of it to the great good and comfort of the public. No other piece of apparatus in the field of electrical engineering has been lauded higher or been the subject of greater abuse, and to all it has served a purpose.

To-day the transformer occupies a higher position than ever before, and it grows in importance as each new development in the field of applied electricity points out a new department of usefulness for it.

There has, however, been enough agitation lately on the part of manufacturers, in behalf of substituting new types of transformers for the old ones now in use, and of relegating the small transformer to the scrap heap, to cause the central station men, who are responsible for the successful operation of alternating current generating plants, some unrest. The foundations of many of these plants were laid before the time of skilled designers of electrical machinery, and at a period when the factory motto was "cut and try." As the public demands increased, the plants developed and expanded before the practical men were amenable to "theories," and before the exact methods of the laboratory had become the daily practice of the constructing engineer. Managers see that engineers are still making mistakes, and that faulty design is still a factor in electrical development, and when they call to mind the enormous sums of money that have been spent in this country on ill-advised improvements it is not to be wondered at that they hesitate.

There is, however, a gradual change for the better in the number of the yearly contributions to the records of our electrical societies, and as these records are the expression of the best thoughts of the men who have made America famous as the land of electricity, they may be taken as signs of the times in our department of engineering activity.

We are constantly impressed with the fact that the refinements of exact scientific methods are being made the subject of everyday discussion, and that the more difficult problems of the technical side of the profession are being so well elucidated by our "practical theorists" that it is possible for all of us to enjoy a concrete appreciation of electrical science without an excessive expenditure of mental energy on the theoretical.

We are coming to a time when exact methods will be the universal rule and when the reputation of having a high "guessing factor" will no longer be a sufficient recommendation.

These influences are noticeable in the improved electrical intelligence of our workmen, as well as of our station engineers, and I find that it extends even to the general public. Indeed, a careful record of the number of times that I am asked "how does the little trolley wheel push the car along?" shows a yearly decrease of nearly 50 per cent.

So we see that matters adjudged to be of slight importance a few years ago are being allotted their normal position. A fault is a fault at the present day, and is not often disregarded as "too small to be appreciable." The old saying that "if you take care of the pennies, the dollars will take care of themselves" applies just as well to electrical engineering as it does to other professions, and it is the "pennies" that I am about to deal with.

Our principal manufacturing companies freely advertise and guarantee the specific economic performance of which each and every one of the transformers that they place upon the market is capable. They severally advertise to supply us with transformers equaling in efficiency, regulation (and what not) any other transformer that can be found upon the market.

The manufacturing companies are unanimous in their guarantees of high efficiency, low core losses, negligible aging and close regulation. If we can purchase transformers freely on these representations, with sufficient guarantee that the specifications advertised are strictly conformed to or improved upon, there is little to be desired on the part of the purchaser over and above what is offered. Any slight improvement that it shall be possible to make upon the best of the performances advertised by the competing factories will be forthcoming in consequence of the rivalries of trade, and the purchaser need only seek now for means of protecting himself against occasional faulty manufacture.

When, therefore, we consider the perfection to which this type of apparatus has been brought, in its every detail, and in sizes varying in capacity from a fraction of one to over 800 kilowatts, we have cause for congratulation.

If you have followed the design and manufacture of the commercial transformer, I think you will admit that at the present time the best of them are figured just about as close as is possible, and in fact we have almost reached the point beyond which any further advance in the direction of improved efficiency must be made by getting better insulating materials, requiring less space and giving this space to the iron and copper.

With a view to investigating the present status of the transformer and the ability of transformer manufacturers to meet in all cases the exacting specifications which they have laid down for themselves, I have had a number of transformers of recent design tested in the Purdue laboratories within the last year. The results of these tests are especially gratifying when gauged from the standpoint of our present commercial requirements, and to the specialist a detailed statement of the results would be interesting. In view of the fact, however, that the electrical literature of the day contains numerous matters of this kind I will not bore you with many figures, but rather discuss the results in a general way.

With but one exception the transformers tested have surpassed the requirements of the specifications laid down by Prof. Jackson in his excellent article on transformer testing, with which we are all familiar, and generally speaking they have conformed fairly closely to the published guarantees of the companies submitting the transformers for test. To what extent this is true may be better appreciated if I cite one or two examples.

A 2.5 kilowatt transformer was submitted for test that was guaranteed to conform or improve upon the following specifications: Core loss 48 watts, regulation 2.1 per cent., and full load efficiency 96.1 per cent. The test of this transformer gave: core loss 42.19 watts, regulation 1.9 per cent., full load efficiency 96.2 per cent.

The showing made by this transformer is good. The core loss is 5.81 watts less than the stipulated value, and the efficiencies are in excess of the stipulated values. In this case the manufacturers more than substantiated their guarantee, and supplied a transformer that is a greater revenue producer than the specifications call for. If the core iron of this transformer can be relied upon as not materially increasing in its hysteretic loss with age, it is an easy matter to figure the money value of the excess economy that the transformer develops.

Suppose, for instance, a contract should be made for forty of these transformers at $30 each to meet an increase in a station load of 100 kilowatts. On an all-day schedule these transformers would probably carry a commercial load equivalent to full load working for five hours. This assumption may seem to represent a better condition of service than is usually met with in practice, but it is an assumption that is fair to the manufacturer in considering the all-day efficiency. The transformers would therefore be working under no load for 6,935 hours and under full load for 1,825 hours per year, and under the conditions of the test would save 1,794 kilowatt hours to the station. If we figure the cost of producing this power at two cents per kilowatt hour, the saving per year would be $35.88 for the forty transformers, or practically 3 per cent. on the amount invested in the transformers. If this power were sold for six cents per kilowatt hour it would represent a net gain to the purchaser of $1,794 \times .06 =$ $107.64 per year more than he had any right to expect under the contract specifications.

Another 2.5 kilowatt transformer submitted for test is advertised by the makers to show a core loss of 57 watts, a quarter load efficiency of 91 per cent., a full load efficiency of 96 per cent., a regulation of 2 per cent., and a no load current of .1 ampere. Under test it was found to have a core loss of 63.6 watts, a quarter load efficiency of 90 per cent., a full load efficiency of 94.8, a regulation of 3 per cent. and a no load current of .087.

Suppose we estimate the economy of transformers of this type just as we did those of the type previously considered. The forty transformers, working on the same schedule, would waste 4,014 kilowatt hours more power than they should under the specifications advertised. At two cents per kilowatt hour the total money loss would be $80 per year, or over 6.5 per cent. of the cost price of $1,200.

Many engineers may claim that the cost of checking up the performance of the transformers would more than eat up the saving effected by the small margin that these results represent, and in many cases under the present organization this would doubtless be true, but if a well-advised stand was taken by the central station managers for mutual protection the result would be markedly beneficial.

A percentage of the transformer output of each of the manufacturing firms could, for instance, be tested in some one place, where a record of the individual performance of all the transformers submitted for trial could be kept, and not only efficiency, but aging and insulation and temperature trials could be made at a merely nominal expense.

But these examples do not cover the ground. I will cite two others.

In the case of a 15 kilowatt oil insulated transformer, guaranteed to develop a quarter load efficiency of 96 per cent., a full load efficiency of 97.4 per cent. and to have a regulation of 1.77 per cent., the test showed a quarter load efficiency of 94.5 per cent., a full load efficiency of 96.1 per cent., and a regulation of 1.6 per cent. The core loss of this transformer, which operates at 60 cycles, is 186.6 watts, and the specifications under which it was built require that the core loss should be about 150 watts.

It would take seven of these to give an output of 100 kilowatts—and they would cost not less than $115 each. The seven transformers in this case would waste 3,855 kilowatt hours in a year, which represents a financial loss of $77 in one year over and above the loss to be expected. This approximates 10 per cent. of the original cost of the transformers and is an item that cannot be neglected. If, on the other hand, this waste power could be sold at

* Paper read before the National Electric Light Association at its Twenty-first Convention, Chicago, Ill., June 7, 8 and 9, 1898.

six cents per kilowatt hour, it would represent a part of the just return on the investment contemplated when the transformers were purchased, and would mean $221 to the company.

I do not claim that the figures which I present to you cover all the items of expense that enter into the installation of 100 kilowatts—in transformers. They do not, but they do represent a phase of the question that deserves more than passing attention at a time when competition is becoming sharper and sharper.

In what I have so far said I have not touched upon the matter of the aging of the transformer core-iron. In cases where it is appreciable it only serves to aggravate the conditions and make the percentage loss greater. In the same way the cost of production and the selling price of the power both enter as important factors, as well as the cost of the transformers. All of these assumptions I have placed low and they should be regarded rather as pertinent examples of the conditions that exist in large plants. The small plants will be affected by influences of this character to a much greater extent.

I do not wish to tire you with figures, but as I believe you will be interested in these comparisons of guaranteed and actual efficiencies, I wish to call your attention to one more case before leaving this matter. Not long ago a manufacturing company requested permission to send a one kilowatt transformer to the University laboratories for a special test, as the transformer was of a new type and highly efficient. There was no direct guarantee in this case, but the impression was given that the transformer would develop an efficiency equal to, if not exceeding, the efficiency of any other transformer of like capacity on the market. The results of our tests indicated a core loss of 178 watts, a full load efficiency of 82.6, a quarter load efficiency of 62.4 and an all-day efficiency of only 54.5 per cent.

There are probably to-day a goodly number of these so-called "highly efficient" transformers eating up the profits of various of our lighting companies throughout the country, simply for the reason that in many cases business managers of electric light and power plants are not sufficiently alive to the importance of looking after the efficiency of the apparatus forming their equipments just as closely as they look after and check up every item of operating expense and maintenance that is necessitated by the exigencies of the service.

The use of transformers such as the one just referred to would be pitiable. It is fortunate that they do not grow to large proportions, but nevertheless they have a telling effect wherever they fall.

As regards the aging of the modern transformer irons, I hold rather a conservative opinion at the present time. A great deal has undoubtedly been accomplished within the last few years in the way of improvement in this respect, and the modern transformers that are supplied to us for testing show a wonderful gain in efficiency, due both to the lower initial core losses and to the diminished per cent. of these core losses with the aging of the iron.

The general opinion seems to prevail at present to the effect that aging is due directly to the reversal of the direction of the flow of the magnetic flux in, rather than to long continued heating of, the iron forming the cores of transformers, and this opinion is also expressed in much of the printed matter that has come into my hands.

In a lecture delivered by Prof. Fleming he said: "It was also discovered, some time back, by Mr. W. Mordey that prolonged slow heating of iron to only 60 degrees C. or 90 degrees C. has a marked effect on the hysteretic constant, and the result is often to increase this constant two or three times. The effect varies with the annealing of the iron, and in many cases the iron which shows the least hysteretic constant at starting experiences the largest percentage increase of it on prolonged heating. This effect is called the magnetic aging of the iron. Owing to the enormous use of iron for transformer purposes this aging had now become a very important matter.

"The electrician lays no very great stress on the mechanical qualities, such as tensile strength, elasticity and so on, but he requires high permeability, small hysteretic constant and small aging; and the iron and steel manufacturer has been able of late years to meet these new requests by producing steel of the necessary quality. Iron and steel can now be produced with a maximum permeability of 4,000 C. G. S. units, a hysteretic loss of about .15 watt pound per 100 cycles per 2,500 flux density, and of non-aging quality. I do not mean to imply that all these qualities can be equally combined in the same sample, but that the iron or steel can be varied to suit the demand.

"Steel can be produced with a higher permeability than wrought iron for large magnetic forces, and with a superior non-aging quality."

The fact seems to be well established that non-aging transformer iron is a commercial possibility, but the fact remains to be demonstrated practically that material of the necessary quality can be obtained in sufficiently large quantities to supply the demands that are being made upon the manufactories.

Failure in this regard is not the fault of the builders of the transformers, and I have reason to know that there are cases in which disquiet prevails in the minds of managers as to whether or not they are getting what they are paying for. I know that the general claim is made that iron with an "inappreciable aging effect" is used, and I do not wish to go on record as claiming that it is not used, but what I do wish to point out is that there are transformers being placed on the market to-day that do not contain non-aging iron. From a large transformer company I have received notice that "at the present time we have not non-aging iron which will fulfill our specifications of core loss; that which we have on hand will give a core loss of from 20 to 25 per cent. greater than the amount stated in our specifications." At the present time therefore it is needful to make just as careful tests for aging as for efficiency or for insulation, in spite of the fact that the former take a longer time and are therefore relatively more expensive to make.

During the last three months six transformers of different types have been subjected to most carefully conducted aging tests in our laboratories. The completed report on these tests has come to me within the last few days and I can give you a resumé of the results.

The core losses of transformers A and B were high to begin with, the first being 72 watts and the latter 83 watts. The per cent. increase in the core loss of these two transformers does not, however, seem to be as great as the per cent. increase in the core losses of transformers C and D that are of more recent manufacture, and that showed initial core losses of 31.5 and 37 watts respectively.

Transformers B and D are of 1.5 kilowatt capacity and transformers A and C of 2.5 kilowatt capacity. An increase of from 5 to 10 per cent. is shown in all the transformers.

To get an idea of what this means, suppose we consider the effect upon the economy of the 2.5 kilowatt transformers, considered in the second case discussed above of a 10 per cent. increase in the core loss. It will add $1.11 per year to the cost of operating each transformer at two cents per kilowatt hour, or $44.4 for the total number.

This represents an additional gain of 3.7 per cent. per year on the investment in three months, or a possible percentage loss on the investment of 14.8 per cent., after the first year, on the supposition of a uniform increase in the core loss.

These figures are not startling in any way, they are too small for that, but they are matters of fact to be taken into consideration when making investments. The opinions that I am voicing regarding the aging of modern transformer irons are conservative, as I believe the transformers built to-day will show a marked improvement upon the performance of transformers built even as late as one year ago. As far as the aging tests that we have made go to throw light upon the subject, I am inclined to believe that the aging problem has as yet not been solved, as none of the transformers tested have met the requirements of the specifications under which they were submitted, and some have fallen very far short of it. All of the transformers tested were new except transformer A, which at the time these tests began had a core loss already increased to 13 per cent. above its initial value. Transformer A was built about two years ago.

The aging of transformer iron does not increase at a constant rate with the time. The rate of increase diminishes as the service continues, but the increase may go on indefinitely. Until the use of non-aging iron becomes more generally possible than at present, it is probable that it will pay to replace the majority of the transformers placed on market by new ones every few years.

It is our present intention to inaugurate next fall a series of one year aging tests under continuous full load conditions of a representative number of transformers that will be built during the present summer by the manufacturing companies who are interested in having these points thoroughly ventilated, and I trust to be able to publish a record of fine performance in this respect at the time of the completion of the tests.

The correct insulation of transformers is another important point that should be considered by the central station manager. Like many of the problems with which we have to deal in the effort to make the transformer a commercial success, this one seems to be subject to a wide variety of opinion. The oil insulation of transformers has deservedly come into great favor, and where care is taken in the selection of the oils used and in the proper design of the transformer case, high protection is secured. Oil insulation under all circumstances does not, however, secure to the purchaser the protection which he feels he is paying for. The claims that are usually made for the superiority of oil insulation, to wit, that it serves to preserve the insulation from oxidation, reinforces the resistance of the insulation to puncture, reinsulates punctures after the passage of the discharge and facilitates the diffusion of the energy liberated as heat in the core and the coils, can in general be readily substantiated.

My experience, however, is that these statements must be regarded as having only a relative bearing upon the subject. Under certain circumstances the insulating value of an oil will be very materially impaired. We are told that transformers will last indefinitely when insulated with oil, whereas without oil the insulation will be so deteriorated after five or ten years that the transformers should be placed, and it may therefore be a matter of surprise that the insulating qualities of the oil itself are ever seriously diminished. As a matter of fact experiment shows that the insulating properties of the oil commonly used in transformers are increased as their temperatures are raised up to about 110 degrees C., and that if allowed to cool they will not lose their augmented power of resisting a disruptive discharge. This much might be said in favor of oil insulation, in view of this two or three fold gain in insulating power, were it not for the fact that a continued heating of the oil for any considerable length of time changes the oil to such an extent that on being cooled its break-down value will be only about one-fifth of its original value. And therefore an oil insulated transformer that will stand an insulation test of 10,000 volts when new, may break down under a pressure of 2,000 volts after having been in continuous service for a considerable time. Conditions such as will produce a result of this character

are not likely to occur in the case of modern transformers, as the increase in the temperature of even the poorest transformers rarely exceeds 70 degrees C. I have, however, met with cases in which excessive heating has resulted when the transformers were kept continuously in service, and I have also in mind a case in which a good modern transformer was so situated above a tin roof and in a position where it was protected from any breeze that might be stirring, that, when the sun played upon it, its temperature reached perfectly distressing values.

What I have said will serve as a hint of how not to handle a transformer, and the importance of selecting proper places for the location of transformers.

If you will look carefully into the matter you will find that not all of the burnouts are due to faulty construction on the part of the manufacturer. It is my experience that the contractor has been in fault in a fair proportion of the cases in which the transformer and service installation has suffered.

For all commercial purposes the best oils will be found to give thoroughly satisfactory results and retain their insulating properties unimpaired so long as the maximum temperature of the oil does not exceed sixty or seventy degrees centigrade. In making a station test of a transformer, if the rise in the temperature of the windings, as measured by the increase of resistance method, does not exceed fifty degrees centigrade after a ten hours' run at full load, the transformer may be passed as satisfactory in this respect.

In connection with oil insulation it must be remembered that its efficiency as an insulating medium is impaired by discharges in the oil. One of the foremost claims made in behalf of oil insulation is that it will flow in and fill up a rupture in the insulation of the coils. Every electric discharge that takes place through the oil, however, disintegrates and breaks up the normal structure of the oil, and causes carbon and other conducting compounds to form. These will rapidly multiply if the discharges are at all frequent, and will destroy the insulating properties of the oil.

As a case in point, and I presume you may know of other similar instances, I want to call your attention to a very good example of what good practice vs. bad practice will accomplish.

There is a city in the West in which the conditions under which electricity is supplied for incandescent lighting are somewhat unusual. There are two companies interested in the business, and both employ the alternating current converter system of distribution. The plant that is operated by the older company was installed about six years ago, and its equipment has grown slowly from year to year as business expanded. Its development has followed the waves of evolution modifying electric lighting practice within this period with a lag factor approximating 90 degrees. The plant has some strictly modern machinery, but much of the line equipment is old. A number of its transformers have been burnt out on account of defective insulation, some have been burnt out by lightning and some have shown their efficiency by getting so hot when switched in on an all-day schedule, under light load, that the "oil used to insulate them boiled up and over and ran down the outsides of the cases."

It is needless to say that in the latter type of transformer the hysteretic losses were considerable; the transformers were, however, manufactured by a firm of high commercial standing.

The lines of the old company are not protected by lightning arresters except where they enter the station, and the secondaries are not grounded.

The new company has been in operation two years and its plant is thoroughly up to date and highly efficient. Oil-insulated transformers of from 80 to 200 lights' capacity are used, and are kept in continuous service. The transformers are of modern design and stand an insulation test of 7,000 volts, without oil. The lines of the new company run over those of the old company and are protected about every 1,500 feet by lightning arresters. None of the secondaries of these transformers are, however, grounded, and magnetic shields are not used. The new company has never experienced any trouble from burnouts of any kind, although its lines are very much exposed. In a very violent electric storm which occurred some time since, in which the service of the old company suffered in consequence of transformer burnouts, the service of the new company was not interfered with in any way, although lightning struck its lines several times.

There has been a great deal of interest expressed recently in the effort to formulate a definite set of specifications covering the construction and insulation of transformers, with the end in view of decreasing the fire hazard and supplying the necessary protection from loss of life and property to both the producer and consumer of electrical energy.

In a letter that I have lately received from a gentleman who is much interested in the success of this project, he says that after corresponding with a number of makers, engineers and lighting companies to obtain suggestions as to the remedies for the troubles arising from crosses, lightning, insulation, break-downs, etc., the results were very unsatisfactory, as there seemed to be a vast difference of opinion.

I have read a great many articles for and against the use of earthing devices, grounded shields and grounded secondaries, but I am yet to be convinced that the prominent American practice of high insulation resistance to a disruptive discharge and a plentiful use of well-grounded short air-gap lightning arresters, does not give a sufficiently good protection.

As I have already remarked, the number of modern transformers that are reported as burning out is relatively very small. By far the greater portion of the troubles arise from crosses between the high and the low potential circuits, and in such cases the loss must be attributed to faulty installation and not to any imperfection in the transformer.

An oil insulated transformer for use on 2,500 volt primary circuits, or less, having a maximum temperature at full load not exceeding 65 degrees C. and designed to stand an insulation test without oil of 750 volts for five minutes, and a prolonged test of 10,000 volts with oil, will be in slight danger from lightning discharges if protected within a distance of 500 feet by a properly installed lightning arrester.

A transformer should also be able to stand a double primary potential test for five minutes, and the insulation test should be made between the coils and between each coil and the core.

In the case of transformers to be used exclusively on very high voltage circuits these considerations do not apply, nor should this paper be considered as dealing with this class of alternating apparatus, which has come to form a department by itself.

In considering the economy of transformers, the problem before us is not so much a discussion of their efficiency as a converter of electrical energy, as it is a discussion of this efficiency in connection with the numerous extraneous causes that tend to make the transformer a menace to life and property.

To my mind a great deal would be gained if an understanding could be brought about between the makers and purchasers of transformers that would result in a uniform practice in the several departments of transformer design. The manufacturers would work to better advantage by having definite specifications to work to, and the way would be open for a bonus or forfeit in equitable proportion to an excess of or shortage in the economy of the product. The fad at present tends toward over-protection. It is bad practice to run to extremes in any department of engineering, and too much protection may turn out to be just as costly as too little.

TWO-WIRE DISTRIBUTING SYSTEMS AND LAMPS, 200-240 VOLTS.*

BY JOHN W. HOWELL.

Distributing systems, operating at 200–240 volts with simple two-wire circuits, first attracted attention about four or five years ago. These early plants used two 110–120-volt lamps in series and were installed as a means of competing in cost of installation with three-wire plants without resorting to the alternating current system, with its disadvantages where motors are operated.

The growth of these plants was slow until the demand created by them led to the production of the 200–240-volt lamp, and practical experience had shown the weakness of these lamps and led the makers to overcome the difficulties met in their manufacture.

What these weaknesses were can be judged by the following extracts from previously published articles:

"The consensus of opinion at the present day of the average types of high-voltage lamps undoubtedly points to the fact that a large percentage are expected to short-circuit as soon as they are put up, and I have heard several engineers say that they expect about one in twelve to go in this way.

"There is no doubt whatever that almost all the present day 200-volt lamps are only suitable for burning in a vertical position. As soon as any other position is adopted defects become prominent. The long thin filament soon drops onto the bulb and cracks it. Also electrostatic attractions, owing to higher voltage, cannot be resisted by the long thin filament, and this is an additional cause of the filament approaching the bulb.

"The effect of electrostatic attractions on long thin filaments is even noticeable with lamps burning in a vertical position."

These are extracts from a paper read by Mr. G. Binswanger Byng before the British Institution of Electrical Engineers on February 24, 1898.

These defects have been entirely remedied, and the experience of many plants operating 200–240-volt lamps during the past year proves these lamps to be just as reliable in service as are 110-volt lamps. The development of the lamp has taken considerable time, and the growth of the 200–240-volt 2-wire system, in spite of the shortcoming of the early lamp, is due to compensating advantages in other elements of the system.

These advantages over the three wire system are—(1) cheapness of installation, and (2) simplicity of operation.

1. Cheapness of installation of the 200–240-volt 2-wire system, when compared with the 110–120-volt 3-wire system, arises from the use of a single large dynamo where the three-wire system requires two, each having half the capacity; with the accompanying duplication of regulating apparatus, indicators, ammeters, etc. There is also a saving of the entire cost of the neutral conductor of the 3-wire system, which conductor in street mains (as distinguished from feeders) and in house wiring should be as large as the outside wires.

Three-wire plants in cities, whose business warrants the employment of the skill necessary to operate the system to best advantage, successfully use 110–120-volt 3.1 watts per candle lamps and get very excellent results from them. The 200–240-volt 2-wire system cannot be considered a competitor of the 3-wire system under these conditions, since the best 200–240-volt lamp on the market to-day is a four watts per candle lamp. But it is my opinion that in smaller installations, whose conditions call for a 3.5 watts per candle lamp when a 110–120-volt 3-wire system is used, the advantages of the 2-wire 200–240 volt system are sufficient to offset the dis-

*Abstract of paper read at the 15th General Meeting of the American Institute of Electrical Engineers, Omaha, June 27, 1898.

advantages of a 4 as compared with a 3.4 watts per candle lamp. Under normal conditions the performance of the present four watts per candle 200–240-volt lamp as regards life and maintenance of candle power is about 25 per cent. poorer than the present 3.5 watts per candle 110–120-volt lamp, but it is my opinion that the greater irregularity in pressure ordinarily found in the 3-wire plants we are now considering, as compared with the 2-wire plants operated under similar conditions, fully counteracts by its injurious effects upon the lamps, the advantage in life and candle power which the 110–120-volt 3.5 watts per candle lamp has under normal conditions over the 200–240-volt four watts per candle lamp.

2. In considering the relative advantages of the two systems, in the case of moderate sized plants above referred to, we must charge against the saving effected in a 2-wire plant by its single equipment and omission of the neutral conductor, the increased capacity of machinery and conductors made necessary by a four watts per candle as compared with a 3.5 watts per candle lamp.

Considering the copper required by a 220-volt 2-wire system using four W. P. C. lamps as our unit, the copper required by the two outside conductors of a 110-volt 3-wire system using 3.5 W. P. C. lamps will be .875. The amount to be added to this for the neutral conductor will vary somewhat with location of the station with reference to the points of consumption. If we assume that one-half the copper is installed for feeders and one-half for the distributing mains, and that the neutral wire is one-third the size of the outside wire in feeders and the same size in mains, then the total copper in the neutral conductors of feeders and mains will be 29 per cent. of the amount used in the 2-wire 220-volt system, and the total copper used in the 110-volt 3-wire system will be 16 per cent. greater than the copper used in the 220-volt 2-wire system. This comparison of the cost of copper does not consider the cost of wiring customer's premises, which is usually borne by the customer; it is, however, an advantage to the 220-volt system that this wiring will require at least 20 per cent. more copper for the 3-wire 110-volt system than for the 220-volt 2-wire system.

The 4 W. P. C., as compared with the 3.5 W. P. C. lamp, would require for the 200–240-volt 2-wire system one-seventh greater capacity of boilers, engines and dynamos than would be required for the 3-wire 110–120-volt system.

The duplication of apparatus required for the 3-wire system will only partly offset this increased cost in the 2-wire 200–240-volt system, but the cost of this duplication of apparatus, together with the increased cost of copper required, will in many cases make the cost of installation of the 3-wire system at least equal to that of the 200–240-volt 2-wire system, leaving the simplicity of operation of the 2-wire system to be balanced against the increased cost of fuel required to operate 4 W. P. C. as compared with 3.5 W. P. C. lamps.

During the time the plant is operated considerably below its rated capacity, which will probably cover even the maximum load during the first year of the plant's existence, and all but three or four hours per day at all times, I think the increased fuel consumption due to 4 W. P. C. lamps will not be appreciable because of the poor efficiency of boilers and engines with light loads, and the total increased consumption of coal during the year will, I believe, be a small consideration under most circumstances, and in my opinion not enough to balance the simplicity of operation above noted.

A few months ago I made a trip through some of our central States, visiting a number of 200–240-volt plants to get a knowledge of the practical workings of the systems from the persons actually operating them, hoping to get from their experience, information concerning existing conditions which would be of value in the lamp factory.

Naturally, my first question to the man who operated the plant concerned the lamps; were they generally satisfactory? were they long lived? did they ever explode? I was greatly pleased with the answers I received. The lamps were reported to be almost universally satisfactory. They were very long lived—in fact too long lived, for better service would be rendered if the lamps were renewed when they began to get dull, and not allowed to remain in service after they ceased to give a first class light.

These 4 W. P. C. 200–240-volt lamps may be used for 600 hours and still give a good light, but I think this is about the limit of their useful life. If not taken in they will keep on burning for a long time and will give an average life of over double that figure before breaking.

The reports concerning exploding were equally satisfactory. For the past year or more exploding lamps had been practically unknown; previous to that time, however, this had been one of the most serious objections to the system.

All these plants have been installed with switches, cut-outs and other appliances made for 110–120-volt installations, and it is remarkable how little trouble has been caused by them.

SOCKETS.

Ordinary key sockets have been freely used, and experience has shown the Edison screw socket and lamp base to be preferable to other types. Some engineers recommend keyless sockets and good snap switches to avoid possible failure of the key socket to break the circuit.

In order to get the desired factor of safety a company has recently developed a special key socket for this work, having a break gap twice as great as the sockets designed for 110–120-volt systems, and having a fiber insulating lining between the outside shell of the socket and the screw shell which is connected with the circuit. This fiber lining projects sufficiently beyond the screw shell to prevent contact with the circuit when the lamp is in the socket. The lamps are provided with short bases designed to be completely covered with this fiber lining, so it is impossible to get a shock by touching the lamp when it is burning.

FLEXIBLE CORD.

Flexible cord has been freely used and is all right if the best quality is used. For this purpose the conductors should be covered with rubber one-thirty-second inch thick and the outside covering should be silk, or if cotton it should be slicked with a compound which makes it non-inflammable.

ROSETTES.

Rosettes designed for 110–120 volt circuits having fuses have given a good deal of trouble, so it has become good practice to leave out the fuse wire and put copper wire in its place, thus having no fuse between the lamp and the fuse block close to the switch controlling the circuit.

CUT-OUTS.

Fusible cut-outs designed for 110–120 volts have failed in many instances, and have often proved much more fusible than their makers expected them to be.

A complete line of fuse blocks carrying special 200–249-volt fuses has been developed recently. These are fitted with the cartridge type of fuse, the fuse being contained in a tube which is provided with brass terminals which fit in spring clips on the fuse block. The fuse wire is inside the tube and is soldered to the brass terminals. The tube is then filled with a plaster compound which smothers the arc formed when the fuse blows. These fuses have been severely tested with 500 volts and currents many times their rated capacities and have always opened the circuits without a flash.

SWITCHES.

Standard knife switches or quick-acting snap-switches having large break distances should be used. Such switches specially designed for 200–240 volt installations are now being developed.

WIRING.

Standard methods of wiring for 110–120-volts are approved for 220–240-volts. Good rubber-covered wire run on porcelain knobs or cleats is specified by the fire underwriters.

ARC LAMPS.

Good arc lamps burning two in series on 220-volt circuits are on the market. Each lamp is provided with an automatic cut out which throws an equivalent resistance into the circuit when one lamp is extinguished, thus permitting the use of one lamp if desired.

FUTURE.

The future of the 200–240-volt system depends largely upon the development of a more economical lamp. All other elements of the system can be made entirely satisfactory with the means and knowledge now at our command, but the production of a more economical lamp calls for an advance in the art of lamp manufacture. That this advance will be made and a more economical lamp will be produced I have no doubt, and hope to see such a lamp placed upon the market at an early date.

A NEW OUTLET FOR ALUMINUM.*

The supply of a material and its consumption sometimes fall out of step with each other. A given manufacture may be so greatly improved as to turn out a product in abundance a little embarrassing to a not too absorbent market. It has been said that some such trouble has made itself felt in the aluminum history. Whether this is true or not, it is certain that one of the largest and most flourishing of our electrolytic manufactures will welcome a new outlet which will aid it in expanding freely and naturally without fear of superabundance of supply. Dr. Goldschmidt, of Essen, at the recent annual meeting of the German Electrochemical Society, held at Leipzig, went far to show that such a use as we have indicated has arisen and may be extended. The experiments of numerous observers have demonstrated that aluminum, on account of its high heat of combination, can be used to reduce the most refractory oxides, and that the rise of temperature accompanying the reaction is commonly so great that the reduced metal is fused into a reguline mass at the moment of its reduction. In this country Mr. Vautin was, we believe, the first to apply this principle to the preparation of refractory metals, such as chromium and tungsten. The system has been improved and made a commercial success at Krupp's works at Essen, and Dr. Goldschmidt, who we understand has worked in conjunction with Mr. Vautin, is largely responsible for this development.

In the earlier experiments the substance to be reduced, say chromic oxide, was mixed with aluminum in powder and the mixture heated in a crucible. This procedure presents certain defects. The heat being applied from without and to the whole mass, frequently induced a reaction so violent as to be explosive, and as a consequence the air was thick with comminuted crucible. A remedy for this was found by igniting the mixture of aluminum and the refractory oxide to be reduced, by means of a fuse composed of material such as powdered aluminum and an easily reducible oxide or peroxide which could be fired at a much lower temperature than that necessary for starting the reaction between the main constituents of the mixture. By this means the temperature of *one part* of the charge is brought to its reaction point while the rest remains cold, and the reaction thus induced is gradual and not explosive, and is altogether more controllable.

There are two uses to which this method can be put. On one we have touched, viz., the preparation of difficultly-reducible metals; it is to this that we owe the considerable masses of chromium and its

* From the *Electrical Review*, London.

alloys which are now obtainable at a relatively cheap rate. The other is a highly ingenious application of the same principle to a totally different object, viz., the uniform and powerful heating of particular parts of metallic objects—in a word, for fusing, autogenous soldering, brazing or annealing. It suffices to surround the portion to be heated with a mixture of powdered aluminum and a cheap difficultly-reducible oxide, *e.g.*, ferric oxide or silica, and to kindle the mass by a fuse of aluminum and an easily-reducible oxide; the parts embedded in the mixture are thus raised to a temperature which can be adjusted with precision by using a charge of appropriate size. The method may prove a formidable rival of other methods of jointing by means of heat, such as hard soldering and electric welding. As compared with the latter, the heat, although kept well to the parts to be joined, is nevertheless less severely localized, and this is sometimes a sensible advantage.

It is evident that this method of obtaining high temperatures may be regarded as equivalent to the use of a "secondary" or "poleless" electric furnace. These terms are not merely fanciful; they recall the fact that the energy which can be usefully expended for the purposes spoken of above has originally been obtained from the water power employed to produce current for the reduction of the aluminum electrolytically. In the electrolytic aluminum furnace, which may be regarded as a step-up transformer for chemical energy, the very energetic substance, aluminum, has been prepared, constituting a portable source of high temperature heat.

A point of practical importance is that it seems unnecessary to prepare pure aluminum for use as a heating and reducing agent. A crude aluminum, perhaps obtained directly by the electrolysis of bauxite in place of the nearly pure alumina laboriously prepared from bauxite which is customarily needed, may be specially manufactured for such uses. A high content of iron and silicon will be of no detriment to the use of the metal, for both will burn giving much heat. Similarly, when the manufacture of a given refractory metal, say chromium, is undertaken, it is clear that the aluminum oxide produced by the action of the aluminum on the chromic oxide can be reduced again in the electrolytic furnace, any chromium which it may contain being thus returned to the cycle of operations. The question naturally arises whether chromium could not be reduced electrolytically (not simply by electric heating in the manner of Moissan) in a similar way to that employed for aluminum. However this may be, it is certain that all but the largest users at present would prefer to buy their aluminum for the reduction of chromium rather than to set up a comparatively costly plant.

COWPER-COLES'S REGENERATIVE ELECTRO-ZINCING PROCESS.

The first care in electro-zincing is to have a properly prepared surface; all traces of grease and rust must be removed. The grease is usually removed by immersion in a caustic soda solution, about ½ lb. to the gallon of water, or, on the other hand, the grease and the scale are removed by sand-blasting. The more usual practice for removing the scale and oxide, but not the best, is to place the iron work to be zinced in a hot pickle solution containing about 1 per cent. of commercial sulphuric acid. The chief difficulty hitherto experienced in the electro-deposition of zinc has been to keep the electrolyte in working order, as zinc anodes, whether cast, rolled or amalgamated, or in the form of granulated zinc, fail to keep the solution up to its normal strength. This difficulty has been overcome in the Cowper-Coles regenerative process by the use of zinc dust which usually contains 97 per cent. of metallic zinc. The zinc dust or tultz is a grayish amorphous substance, and must not be confused with zinc oxide. It is obtained as a sublimal product in the flues of the zinc smelting furnaces. The zinc dust is placed in regenerating tanks mixed with fine coke or sand upon perforated grids fixed about half way down the tank, so as to form a filter bed. Any free acid present in the electrolyte in passing through the filter bed is neutralized. If the zinc dust is allowed to get into the electrolyte it is found to increase the electrical resistance. A zinc sulphate solution containing 12.59 acid, after passing through a filter bed containing 10 per cent. zinc dust, was found to contain only .68 per cent. of free sulphuric acid. In this way the solution can readily be kept up to its normal state, and quite free from impurities in suspension, which has been found to be one of the chief causes which lead to the formation of zinc sponge. The regenerating tanks are connected to the depositing vat by a system of piping, the electrolyte flowing into the bottom of the depositing tank by gravity, the lighter liquid being drawn off over a sill at the end or in the corner of the vat. One tank discharges the regenerated solution while the other is constantly being filled by a small rotary pump. The electrolyte is composed of 40 ounces of zinc sulphate to the gallon of water, and has a specific gravity of 1.1770 (=19 per cent. of crystallized zinc sulphate). The anodes are made of lead, and the current density is 17 amperes per square foot, the EMF. at the terminals of the generator being 6 volts. A bye-pass is provided so that the solution can be circulated without having to pass through the regenerating tanks.—*Electrical Review, London.*

THE TELEPHONE IN ITALY.

The telephone concession of Florence, says the London *Electrician*, includes the town and the adjoining suburban communes, with a population of about 250,000 inhabitants. The telephone was introduced into Florence by two companies—one Italian and one English—both holding concessions for Bologna as well as Florence, the Italian concession including Leghorn. In 1883 the two companies amalgamated and formed the Societa Telefonica per l'Italia Centrale, with a capital of $300,000. The early concessions granted by the Government had only the duration of three years, after which the Government was at liberty either to renew the concessions, grant new ones, or to establish Governmental telephonic communication. To this latter effect the Government presented a bill to Parliament by which all the existing concessions at their expiration were cancelled without any right of compensation or any obligation on the part of the Government to buy the lines and offices already established. This bill, approved by the lower House, was rejected by the Senate. A new bill was then presented and approved by Parliament by which the right of granting concessions for private or public telephonic communication was entirely reserved to the Government. The law fixed the duration of each concession to 25 years, after which all the plant, line and premises become the property of the State. The Government has also the right after 12 years from the date of each concession to take possession of the concern by paying a sum equal to the average net profit of the three preceding years multiplied by the number of years which each concession has still to run to reach the final period of 25 years determined by law.

The same law establishes a tax of 10 per cent. on the gross profits of each concession for public use, the right of free communication for all the postal and telegraphic offices, and a reduction of 50 per cent. on the public tariff in favor of all Government, provincial and municipal offices. As a compensation, however, the companies have the right to fix wire supports on all public and private properties. When a private proprietor refuses to grant the permission a simple application to the Prefect is required to obtain the enforcement of the law. The proprietor may ask for an indemnity, and if both parties do not agree the Prefect decides if any and what amount for once only is to be paid. As soon as the Italian telephone companies saw their existence insured for a fixed period they began to reorganize their services by changing the apparatus, wires, etc., with the object of diminishing working expenses so as to enable them, besides distributing a dividend to the shareholders, to yearly set apart a sum for the reimbursement of the capital at the expiration of the concession. Experience proved that these objects could not be attained by small companies on account of the heavy expenses of management and the necessity of having a uniform technical direction, and they therefore amalgamated and formed larger companies. This amalgamation is now under execution.

Florence is now a branch exchange of the Societa Generale Italiana dei Telefoni ed Applicazioni Elettriche, with a capital of $1,200,000, and owns the telephonic exchanges of Rome, Naples, Genoa, Palermo, Venice, Leghorn and most other important towns, with the exception of Milan and Turin, where the old local companies have formed the Societa Telefonica per l'Alta Italia. The number of subscribers in Florence is only 900, and the following is the tariff of rates charged:—$32 within 1,093.61 yards from the central office, $36 within double that distance, $40 within three times above distance, and for further distances $1.40 for every 218.722 yards. The apparatus and instruments were wholly supplied by the Antwerp Telephone and Electrical Works. The wire used is silicon bronze for the lines in the interior of the town, and steel or iron for the country. All subscribers have the right to complete service day, night and Sundays.

The operators are females, hours from seven to eight per day, salary from $6.25 to $12.50 per month. A fortnight's leave of absence is granted yearly, and a holiday on each alternate Sunday. Workmen employed in the maintenance of apparatus receive from 40 cents to 62 cents per day; linesmen from 40 cents to 50 cents, with a holiday on every alternate Sunday and a half holiday on Saturdays. All workmen are insured against injury or death, this insurance being obligatory by law. In case of injury full wages is paid during illness, in case of permanent disablement 900 days' wages, and the same compensation is due to the families in case of accidental death. In ordinary sickness workmen are supported by the company for a certain period according to length of service, but in no case under three months. Hours of work ten, with 4 cents for every extra hour. During the summer months a few days' holiday is granted. Each workman has from 150 to 200 instruments to look after.

The original local company distributed a dividend varying from 2 to 3 per cent. The new amalgamation has not yet published a balance-sheet, but it is expected that the dividend, if any, will not be in excess of the above rate. With a 10 per cent. concession tax and 20 per cent. income-tax, and the necessity of refunding the capital, very little extra profit is likely to be available for distribution.

Mica Mining in India.

Mr. Robert W. Thompson, A. M. I. C. E., sent a most interesting article to the *Journal* of the Society of Arts on mica mining in the district of Nellore, India. The author states that mica exists in the western parts of the district, where the land begins to rise to the ghâts. The surface indication of it is the outcrop of quartz and felspar, with which minerals it is usually associated, being sometimes integrated with them so as to form a coarse-grained granite, or else occurring in large separate masses. It is not unusual to find distinct masses of mica, of quartz and of felspar, lying contiguous to each other; the idea which they convey being that nature in-

tended manufacturing granite on the spot, but after collecting the necessary materials had changed her mind about it. But the surface indication above mentioned is not always present: in some cases mica occurs in isolated blocks.

There are mica mines in operation at Inikurti, Utukur, Chaganum, Sydapuram, Khandali, all lying from W.S.W. to S.S.W. of the town of Nellore, at from 20 to 30 miles distance. Indications of mica are met with further north, but no mines have yet been started; the industry is, in fact, in its infancy, the first mine, the one at Utukur, having only been started in 1888. The mineral is found near the surface, and those hitherto engaged upon the getting of it not being professional miners, but mere diggers, the only method of working yet adopted has been that of quarrying—no subterraneous mining has yet been attempted. The mica occurs in masses of from 100 to 200 cubic feet; these masses have been found from near the surface to a depth of 70 feet, the method employed for detaching the stuff being blasting with gunpowder or dynamite.—*Elec. Engineer, London.*

LONDON NOTES.

[From our London Correspondent.]

Electric Tramways at Halifax, Eng.

A four-mile length of electric tramway (overhead wires) has been opened by the Halifax Corporation, current being taken from the municipal lighting station. From its size the line is of no special importance, but for one section, 1½ miles long, there is a continuous climb, averaging 1 in 20, and this will be a good opportunity for electric traction to prove to English eyes of what it is capable. On the ascent it is stated that to propel a car up one of the gradients requires an expenditure of nearly 100 amperes, but on the "down" journey no current whatever is consumed, and in addition to the ordinary brake a special slipper brake has to be employed, while there is also an electric emergency brake. The track is 3 ft. 6 in. gauge throughout, with 98 lbs. girder rails. There was added to the plant at the lighting station for the purpose of the tramways an E. C. C. generator, rope driven, and of the four-pole type. This generator has an output of 220 amperes at 500 volts. There is also to be a motor alternator, a battery of 270 chloride cells and a motor driven booster. As the plant was added at the lighting station the outlay for the necessary new machinery, etc., and alterations to buildings only came to about $40,000. There will shortly be several other local authorities equipping tramlines on the same principle, and this Halifax plant will be watched with interest. It is important to note in this connection that the Dover municipal trams, which have been in operation for not twelve months, have already made sufficient profit on the lines to enable a reduction to be made in the rates. This is a fact which will tell with the municipalities. The Corporation, it may be remembered, has no generating station or plant of its own, but takes its supply of current from the lighting company at so much per unit under agreement. In this way the Corporation is free from heavy interest on capital charges which will be a burden to municipal bodies which have no lighting plant of their own.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

DEATH OF CORNELIUS HERZ.

Cornelius Herz, whose death at Bournemouth, Eng., on the 6th inst., is announced, had some reputation as an electrician, but his work in that direction was principally as promoter of electrical enterprises. His place of nativity is not certain, Besancon, France, and Worms, Germany, both being named in that connection. It is known, however, that his father was a German Jew and his mother a Frenchwoman. When he was quite young his family removed to England, but after a short stay there came to this country and took up their abode in New York. In 1864 young Herz was graduated from the College of the City of New York, and was subsequently sent to Heidelberg, Munich, Vienna and Paris to continue his studies. During the Franco-Prussian war he was appointed assistant surgeon-general in the Army of the Loire, and for his services was decorated with the cross of the Legion of Honor. When the war was over he returned to New York, where he married Miss Bianca Saroni, said to be a niece of the poet Heine. Soon afterward the young couple moved to San Francisco and there Herz started on his career as an electrician and succeeded in establishing an electric lighting system which remains to this day and has expanded into one of the most important business concerns in the city. In 1877 he went with his family to Paris and started on a brilliant career. He overthrew the gas monopoly, and provided the main thoroughfares with electric light. He founded *La Lumière Electrique*, one of the leading electrical journals of France. He established the telephone system of France, organized the first electric exhibition that was ever held, and finally became associated with the Rothschilds in putting into practice the theory of the transmission of force by electricity. At the same time he rapidly became a great social and political figure in the Republic. He was the bosom friend of the prominent men of the day, and rumor credited him with being the power behind the President's chair.

When in 1893 Charles de Lesseps made a clean breast of his transactions in connection with the Panama Canal, Herz was accused of receiving 600,000 francs paid over by De Lesseps in 1886. The cries of "foreign Jew" and "British spy" were raised against Herz in the French Parliament and by the newspapers of Paris. The trial of Herz began on July 27, 1894. He was then at Bournemouth, England. He had been ill, and was not expected to live. The case went against him, and two houses in Paris, the property of his wife, were ordered to be sold. Exhaustive formalities looking to extradition of the fugitive were vainly continued for several years, and Scotland Yard detectives were constantly at Bournemouth.

Herz's downfall was complete. In this country even his right to the title of "doctor" was questioned, and various colleges disclaimed ever having given him a professional degree. In England his sympathizers said that a brilliant man had been hounded to death by the French Government merely because of the unusual circumstance that he, though a foreigner and a Jew, had been high in the Legion of Honor. His grasp of scientific subjects and ability for business transactions were lauded by some and scoffed at by others.

Some months ago he had a claim filed in the Department of State at Washington for $5,000,000 against the French Government, alleging that he was despoiled of his property in France on no other ground than persecution. The matter is still under advisement.

KING LEOPOLD of Belgium has commissioned Mr. R. D. Mohun, United States Consul at Zanzibar, to build a telegraph line from Lake Tanganyika to Wadelai on the Upper Nile. Mr. Mohun will in the work employ none but American and British engineers.

SOCIETY NEWS.

American Institute of Electrical Engineers.

At the meeting of the Executive Committee, June 24, Mr. C. O. Mailloux, of New York, was elected a Vice-President of the Institute to fill the vacancy caused by the previous election of Dr. A. E. Kennelly to the Presidency. Mr. Robert N. Baylis was also appointed a member of the Board of Examiners, succeeding the late Dr. Chas. E. Emery.

The following associate members were elected:

Walter Cummings Allen, Washington, D. C.
Albert H. Armstrong, Schenectady, N. Y.
Geo. A. Damon, Chicago, Ill.
Frank H. Dexter, Ithaca, N. Y.
P. M. Downing, Blue Lakes City, Cal.
Joseph Lyons, Washington, D. C.

The following associate members were admitted to full membership:

Alfred A. Thresher, Dayton, O.
William B. Jackson, West New Brighton, N. Y.
Paul M. Lincoln, Niagara Falls, N. Y.
Thorburn Reid, New York City.
Philip Green Gossler, Montreal, Can.
Theodore E. Theberath, San Francisco, Cal.
Frederick M. Pedersen, New York City.
Will K. Dunlap, Niagara Falls, N. Y.

American Society of Civil Engineers.

The American Society of Civil Engineers will hold its Thirteenth Annual Convention in Detroit July 26 to 29, inclusive. The headquarters of the Convention is to be the Fellowcraft Club, and all meetings will be held there. The programme calls for the opening session of the Convention at 10 o'clock Tuesday morning, July 26. Alphouse Fteley, president of the society, will then deliver the annual address. The next session is put down on the programme to begin at 14:30 o'clock. Then will begin the discussion of the papers. At 16:30 there is to be a trolley ride about the city, tendered by the Detroit Electric Railway; and at 20 o'clock there will be an excursion upon the river by courtesy of the Detroit, Windsor & Belle Isle Ferry Company.

Two sessions will be held Wednesday, beginning at 10 and 14:30 o'clock respectively, the balance of the day being devoted to side trips to points of engineering interest about Detroit. On Thursday the society will go in a body to inspect the Port Huron tunnel. The Grand Trunk Railway has tendered a complimentary train to the society for the trip to Port Huron, the return to be made by steamer. On Friday the Convention will resume business in Detroit, and Friday evening the Convention will terminate with a reception.

The papers to be read at the Convention are:

"Experiments on the Flow of Water in the Six-foot Steel and Wood Pipe Line of the Pioneer Electric Power Company at Ogden, Utah," by Charles D. Marx, Charles B. Wing and Leander M. Hoskins.

"The Determination of the Safe Working Stress for Railway Bridges of Wrought Iron and Steel," by E. Herbert Stone.

"Marine Wood Borers," by Charles H. Snow.

"Dredges and Dredging on the Mississippi River," by J. A. Ockerson.

"Reservoir System of the Great Lakes of the St. Lawrence Basin; its relation to the problem of improving the navigation of these bodies of water and their connecting channels," by Capt. Hiram M. Chittenden, U. S. A., with a mathematical analysis of the influence of reservoirs upon stream flow, by James A. Sedden.

"Three-hinged Masonry Arches: long spans especially considered," by David A. Molitor.

Help to fight the Electrical Trust by subscribing for ELECTRICITY.

LEGAL NOTES.

In Judge Clifford's court at Chicago on the 6th inst. the Hyde Park Electric Light & Power Company confessed judgment on two notes aggregating $20,891, one for $14,891,52 being held by Clarence N. Goodwin. The other was for $6,000, and was held by Robert F. Hall.

The Cornman Company, dealers in electrical supplies, Cleveland, O., have filed a deed of assignment in the insolvency court. Their assets and liabilities are fixed at $10,000 each. A. R. Manning, jr., was appointed assignee.

The Probate Court Judge at Canton, O., has appointed C. C. Davidson receiver of the Alliance Street Railway Company of Alliance, O. The appointment was made on the petition of Henry C. Ellison of Cleveland.

A final decision in the transfer suit at Atlanta, Ga., has been made by Judge W. T. Newman in the U. S. District Court. It forever enjoins the city of Atlanta from enforcing the street car transfer ordinance.

The owners of the Read House, Chattanooga, Tenn., have a large number of storerooms on the ground floor of the building which they let out to various tenants, to whom they agree to supply water and electric lights. Recently suit was brought by the city to compel the owners of the building to pay a license for operating an electric light plant. Judge Estill of the Circuit Court, before whom the case was argued, decided that the Read House people were not manufacturers of light in the contemplation of law, not being in the business to furnish light to general consumers, but only to tenants of their own property.

Judge Lacombe, in the Circuit Court, New York, has granted the application of the Thomson-Houston Electric Company for an appeal to the Circuit Court of Appeals from a decision by Judge Shipman in the Circuit Court, dismissing the company's bill of complaint against the Union Railway Company and the Walker Company. The complainants charged the defendants with infringing a patent for improvements in overhead contact electrical devices or switches. The suit of the Thomson-Houston Electric Company vs. Ed. A. Maher and the Walker Company for a preliminary injunction restraining the defendants from alleged infringement of certain claims in letters patent No. 495,443. granted to Chas. J. Van Depoele, was dismissed.

The State Supreme Court at Indianapolis has overruled a petition for a rehearing in the case of the city of Indianapolis against John N. Navin who was arrested for refusing to pay a 5-cent fare to the conductor of a car of the Citizens' Street Railway Company. The suit was brought to test the constitutionality of the 3-cent fare law, Judge Showalter of the Federal Court having granted an injunction against the enforcement of the law. The Supreme Court takes issue with Judge Showalter in the following somewhat egotistical passage from its decision: "We (the Indiana Supreme Judges) are constrained to adhere to our original opinion that the act in question, even if local and special, is not in contravention of any of the provisions of the constitution of this State as contended by the appellant. As to questions arising under the constitution of the United States, we should be constrained to follow the adjudications of the Supreme Court of the United States without in any wise considering whether such a construction should or should not commend itself to our independent judgment, but upon the requirements of the constitution of the State we are not at liberty to set aside or discard our own views, because of the fact that they do not meet with the concurrence or approbation of any other court however high, or any judge however eminent."

Judge Kilpatrick, at Trenton, N. J., has issued a temporary injunction in the case of the Sprague Electric Railway & Motor Company against the Camden & Suburban Railway Company. The latter has five trolley cars purchased of the Walker Company which are equipped with motors which the courts have pronounced an infringement of the Sprague patent.

At Milwaukee, Wis., on July 6, Judge Seaman, in the United States Circuit Court, handed down his decision in the suit of the Western Electric Company against the American Rheostat Company and others of Milwaukee, in favor of the petitioner. The effect is to prevent the defendant company from further manufacturing of electric cutouts or rheostats, the Court deciding that the defendant has been infringing upon the patent of the complainant.

In the matter of the application of the Baldwinsville (N. Y.) Telephone Company for a peremptory writ of mandamus, Justice Hiscock has denied the application with costs. The application was to compel the Central New York Telephone & Telegraph Company to place in the office of the petitioner "one of its telephone instruments with the usual and proper wires and connections and to allow said Baldwinsville company the proper and usual and customary use of said telephone wires and connections." The petitioner's claim was that a request was made of the defendant to place a telephone in its office at the regular price; no telephone was thus placed and his application for telephone service was duly filed. The petitioner based his claim for relief upon the general obligations which the company by entering upon a general telephone business incurred. The judge holds that a reasonable construction of the statute does not require one telephone company to supply connections with its system to another company, so that the latter may utilize the connected system as part of its own and transmit thereover its own messages on payment of the merely nominal sum required of ordinary subscribers.

Personal.

The *Electrical Engineer* has recently added to its editorial staff Mr. Max Lowenthal, who will hereafter hold the position of associate editor on that well-known weekly. Mr. Lowenthal would seem eminently fitted for the duties he will be called upon to perform, having studied extensively abroad, and having graduated at the head of his class in electrical engineering from the Hebrew Technical Institute, and also holding the degree of E. E. from Columbia University. Mr. Lowenthal was for some time in the testing rooms of the Western Electric Company, and later had charge of the testing department of the Schuyler Electric Company at Middletown, Conn. He has been a frequent contributor to a large number of electrical journals, is a member of the New York Electrical Society and an associate member of the American Institute of Electrical Engineers. We wish him success in his chosen field of labor.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING PLANTS.

Algona, Ia.—An electric light plant is being erected here at a cost of about $15,000. The contract for the machinery has been given to Mr. Bigelow of Lincoln, Neb. The plant is to be first class.

Bunker Hill, Ill.—An electric light plant will be established here for which about $7,000 worth of bonds will be issued.

Duluth, Minn.—The lighting problem is bothering the city fathers. The city now pays $50,000 yearly for its lights and it is proposed if the cost is not materially reduced by the electric lighting company to substitute some other system of illumination. The lighting company's contract expired a few weeks ago, but the service will be continued at the contract price until some decision is reached by the council.

Flatonia, Tex.—The electric plant, now under construction, will be ready to operate in a few weeks. About 450 lights have been subscribed for.

Flint, Mich.—Receiver Clarence Tinker has been ordered by the court to sell the Fenton electric light plant to Fayette Thompson, whose bid was $9,000.

Hagerstown, Md.—The street commissioners have rejected the proposition of the Hagerstown Electric Railway Company to light the town for $77.77 a light annually on a ten year contract. Public sentiment is in favor of the building of a municipal plant.

Holyoke, Mass.—The board of public works has requested the city solicitor to give his opinion as to the rights of the city in securing electric light service when the present contract expires.

Jamaica, L. I.—The electric light company cut off its lighting service on Friday night because Controller Coler refused to pay the bills of the company, amounting to $22,000.

Lebanon, Pa.—Proposals will be received until August 2 by the police committee of this city to furnish the city with electric street lighting, beginning June 1, 1899, to consist of not less than 125 arc lights of 2,000 candle power each, burning every night from twilight to dawn. Proposals to be contingent upon a contract for five years, also for ten years, and price per lamp per year to be made accordingly.

McArthur, O.—The town council has voted to issue $5,000 worth of bonds to install an electric lighting system.

Nashville, Tenn.—Postmaster Wills has secured an allowance of $3,000 from the Department at Washington to be expended upon new electric lights for the city post office.

Providence, R. I.—The contract between the city and the Narragansett Electric Lighting Company has been ratified by the council. The contract runs to the year 1912. The terms of the new contract, in a general way, are that the Narragansett Electric Lighting Co. agrees to bury its high tension wires and in addition to provide a sliding scale of prices which, covering the period to the time named above, gives a distinct and steady reduction in the price of the city lights. The company also agrees to pay 5 per cent. of its gross receipts to the city. The only opposition to the adoption of the new contract was suggested by the advocates of a municipal plant, and this dwindled away in view of the general belief that rates offered were far lower than those secured in the municipal plant experiment.

Topeka, Kan.—The Executive Council has decided to light the State House by an independent plant and has made a contract with the Fort Wayne Electric Corporation for the machinery.

Westbrook, Me.—The city council has directed the committee on lights and water to advertise for bids for the construction of a municipal electric lighting plant to cost about $4,000.

West Superior, Wis.—The proposition of the Water, Light & Power Company for a five years' lighting contract here has been accepted by the council, ending a negotiation which was opened over a year ago, when the city complained that it was costing too much for lights. The city takes 150 arc lights at $100 each per annum.

STREET RAILWAYS.

Akron, O.—A new company has been organized to build an electric railroad from this city to Cleveland. A gang of surveyors are now at work laying out a route.

Brooklyn, N. Y.—The Nassau Electric Company has made a test of a new combination car which is the idea of President Albert Johnson of the company and which appears to meet the requirements of the road better than any other style in use. The car is entirely closed upon one side, preventing either egress or ingress upon that side. The other side is open, and is equipped with sliding doors, which can be closed or opened to suit the weather conditions. The sliding doors, when opened, make the car practically an open car and when closed make it a closed car. The large windows in front and at the rear of the car likewise open and let a free sweep of air through. The only ingress and egress is at the right side where there are sliding doors, and the seats are placed back to back. President Johnson proposes to build 180 of these cars this summer, and to transform as many of the old-fashioned open cars into the new style. The car is said to have the advantage over the ordinary closed car that it will seat fifty passengers, while the old will seat but twenty-six people. —The Brooklyn Heights Railroad Company has begun work on the Sea View Elevated Railroad property, which runs between Coney Island proper and Brighton Beach. The improvements include the building of several hundred feet of bulkhead and the filling in of property which will reclaim several thousand square feet of ground. Two terminals are to be built—one at the entrance of the Brighton Beach Hotel and the other at the Brighton Beach racetrack. It is expected that the work will be finished within two weeks, and the cost is estimated at $20,000. The old engines and cars that have been used for the past years will be abolished and electric motor cars will be substituted.

Charleston, S. C.—The Charleston City Electric Railway Company has just reached its first anniversary and the enterprise has proved a success. The road has paid its way from the start, and has not only earned its fixed charges, but is able to pay a dividend of 5 per cent. on its stock and leave something to place to surplus.

Chelsea, Vt.—An electric railway is proposed to connect Chelsea and South Royalton and to be equipped for passengers and freight.

Delaware, O.—The Delaware Electric Street Railway has been appraised by order of the Common Pleas Court at $15,900. The road cost $75,000 and has been offered at public sale four times by the receiver and returned for want of bidders.

Detroit, Mich.—Leading business men have signed a petition to the common council for an ordinance permitting the street railways to carry light freight.

Grand Rapids, Mich.—The Grand Rapids & Lake Michigan Electric Railroad Company intends to apply to the common council for a franchise to occupy certain streets in this city as a part of the direct line to Holland and Macatawa park which will be constructed this season. The company has the right of way already acquired from Macatawa park to the city line, and the franchise asked for will give it an entrance into the city.

Greensburg, Pa.—The Greensburg, Jeannette & Pittsburg Electric Street Railway, between Greensburg and Manor, has changed hands. A syndicate composed of Harrisburg capitalists has purchased it. Benjamin Myers and Patrick Russ of Harrisburg are the principal members of the new company. C. L. Brinser of Harrisburg was elected superintendent of the company and has taken charge of the line. It is the intention of the new company to improve the road and rolling stock and extend the line to Irwin this summer. The company also proposes purchasing the Greensburg and Hempfield Electric Street Railway, between Greensburg and Huff, changing it to standard gauge and extending it to Mt. Pleasant.

Lowell, Mass.—The Clinton selectmen have decided to grant to the Clinton, Hudson, Maynard & Concord Street Railway Company a franchise to build and operate an electric railway from the "Acre" in Clinton to the Berlin town line. This practically puts an end to the hottest struggle for a franchise between rival companies that any town in Massachusetts has had.

St. Louis.—The State Supreme Court handed down a decision sustaining the action of the State Board of Equalization to compel the street railway companies of St. Louis to make their official returns to it instead of to the city, as they have been doing. The court held that it was unconstitutional to render such returns to the city.

Petersburg, Va.—The Piedmont Traction Company has petitioned the council for right of way through the streets of this city for a new electric railway.

Peekskill, N. Y.—The highway commissioners of the town of Cortland have granted a franchise to the Peekskill Traction Company to build and operate a trolley railroad on certain highways.

Providence, R. I.—The New York, New Haven & Hartford Railroad Company, it is stated, intends to operate the road between this city and Warren and Bristol by electricity.

Minneapolis, Minn.—The board of trade at a recent meeting adopted a resolution congratulating the Twin City Rapid Transit Company upon the excellent service inaugurated in the new Interurban line.

Trenton, N. J.—At a recent meeting of the stockholders of the four street railway companies concerned it was voted to consolidate the Trenton Passenger Railway Company, the Ewing Passenger Railway Company, the Mulberry Street Railway Company, and the Pennington Avenue Passenger Railway Company. The new company will be named the Trenton Street Railway Company.

TRANSMISSION PLANTS.

Little Rock, Ark.—There is talk of "harnessing" the Ouachita River at or near Malvern for the production of electric power. It is estimated that 5,000 horse power can be made available at Malvern.

Oakland, Cal.—The Oakland "Examiner" says: "The company which is developing a water supply and electrical power in Sutter Creek, Amador county, of which W. Frank Pierce is president and manager and T. C. Bullock superintendent, is preparing to transmit energy to the bay cities. The authorized agent of the company, Attorney George De Golia, has petitioned the board of supervisors for permission and franchise to erect telegraph poles through Alameda county to the plant for the conveyance of electrical currents. The following roads are named in the petition: Oakland & Haywards County road, San Ramon road, Crow & Norris Canyon roads, Redwood Canyon road, Cull Canyon road, Castro Valley road and Lake Chabot road. The matter was referred to the franchise committee."

MANUFACTURING, ETC.

Cleveland, O.—The Walker Manufacturing Company has secured the contract for erecting the extensive electrical plant of the Union Carbide Company of Chicago, to be erected at the falls of the Sault Ste. Marie.

New York.—The Journal of Commerce says: "The opportunities for the sale of electrical railway equipments in Japan are becoming evident. The Tokio Electric Railway Company and the Tokio Electric Car Railway Company have been organized, and, according to the latest report, they will re-equip the existing horse car lines in Tokio and build new electrical railways. The first-named company has at present a capital of $2,500,000, and will control all the lines in the eastern half of the city, aggregating 100 miles of track, to be built within five years. Twenty miles of horse car line is to be changed to electricity. The second-named company will operate the lines in the western portion of the city. Additional roads, aggregating about 200 miles, will be taken up by each company upon the completion of the first 120 miles by each. An estimate on the first 50 miles of road, including the entire equipment of cars and the power station, is placed at more than $2,000,000. A central power station will be built on the river about five miles from the center of the city, and power will be delivered to the trolley lines by eight transformer stations, placed at convenient points in the city. The roads are to be double-track. There is also in contemplation, according to the advices, a suburban line between Tokio and Yokohama 18 miles in length. In nine other cities and towns the arrangements are said to be under way for the construction of 135 miles of road in all."—The General Electric Company, it is announced, will within a few days ship the first of the electric motors to be used on the London Underground Railroad.

St. Louis.—President Julius S. Walsh of the Terminal Railroad Company is reported to have said that after a thorough search he has failed to find any practical plan by which the steam engine now used in the tunnel and railroad yards can be satisfactorily replaced by electric motors. The large number of trains hauled daily by the company in the St. Louis and East St. Louis yards and through the tunnel, could not, so Mr. Walsh avers, be properly cared for with the electrical engines now obtainable.

COMPANY MATTERS

Duluth, Minn.—On the application of Thos. Lowry, of Minneapolis, one of the stockholders, L. Mendenhall, the president, has been appointed receiver of the Duluth Street Railway Company. It is explained that this is the beginning of reorganization, made necessary by an excessive capitalization and shrinkage in Western business and values since the panic of 1893. It is not caused by any pressing exigencies or dissension. The present management will continue.

Jamaica, L. I.—The Queen's Borough Electric Light & Power Company, recently incorporated, has absorbed the Cittzens' Company of Far Rockaway. In order to meet this transaction and for other purposes, the Queen's Borough Company has executed a mortgage to the Colonial Trust Company of Manhattan, and has issued bonds in $250,000 of $1,000 each, at five per cent., maturing in 1928. The principal stockholders of the new organization are Royal C. Peabody, Van Wyck Rossiter, Joseph C. Biglin, Frank MacGovern, Isaac M. Sutton and T. S. Williams.

Orange, N. J.—The property and franchises of the Suburban Traction Company were sold at auction by the master in chancery on the 7th inst. The only bid, $100,000, was offered by Col. Charles A. Sterling, of East Orange, representing the new Orange & Passaic Valley Railway Company, and the bid was accepted by the master. Although organized as an independent concern, it is admitted by trolley men that the Orange & Passaic Valley Company is to work in harmony with the North Jersey Traction Company and practically will be under the same general management. The purchase price paid by the Orange & Passaic Valley Company for the road will just cover $67,000 in certificates issued by Watson Whittlesey, the receiver, in whose hands the company has been for three and a half years, about $8,000 interest on same, and $25,000 in costs of court and lawyers' fees. The new company also assumes the payment of $60,000 of first-mortgage bonds, and a guaranteed loan of $150,000 made by the Manhattan Trust Company of New York upon second-mortgage bonds.

ELECTRICIANS IN THE WAR.

Col. Eugene Griffin is at Camp Townsend, Peekskill, organizing the First Regiment of Volunteer Engineers, which he will command. The second battalion is already completed. Company L was mustered in on Friday last. The 2d Battalion of the regiment, organized on Saturday, is composed of Companies E, F, G, H. Major Louis Duncan is commandant of the battalion.

PERSONAL AND MISCELLANEA.

Moses D. Crane, inventor of the fire alarm telegraph, is reported to have taken his own life at Newton Highlands, Mass., on Thursday morning last.

The latest fad among Paris women is the operating of automobile vehicles, and the Duchess d'Uzes has already been arrested and fined for riding at a forbidden speed. To be an authorized driver of one of these machines it is necessary to pass an examination, and large numbers of women are taking the examination, while the tailors are hard at work devising something original in "automobile costumes."

The Pittsburg "Press" states that "J. W. Sweeney, constructing electrical engineer in the employ of the Westinghouse Company, will sail for England July 15, to install the big dynamos and electric light and power plant for the Metropolitan Electric Company of London. The equipment was made at the Westinghouse plant and shipped to London June 20."

The inventor in his researches after the unknown has sometimes to face dangers equal to those that lie in the path of the warrior. Thomas A. Edison, Jr., admits that he is constantly in fear of bodily injury from his experimenting. He has met with several accidents of more or less magnitude already, and he is still almost a youth. "One lesson I have learned," he says, "and that is to be vastly more careful in making experiments. I consider I am a cautious man at all times, but the several narrow escapes I have had make me thoughtful. But I never expect to die a natural death. I feel confident I will be blown up some day. Or failing in an explosion, some sudden shock will pick me off in a wink. I do not see how it can be otherwise if I continue experiments such as I have been carrying on. Caution is absolutely necessary, and exceedingly great caution, but an inventor deeply engrossed in an experiment is the last man to be cautious. He must concentrate his mind severely on the task before him to derive the benefit of the experiment, and when his mind is so closely concentrated his own welfare is the last thing he considers."

According to the Detroit, Mich., "News" the League of American Municipalities will have a gay time when it meets in Detroit next month. The Citizens' Executive Committee has decided to spend $1,000 for a trolley ride and lunch at the water works park, $3,000 for a boat ride up the river, with refreshments, $2,000 for a night trip to Belle Isle with "lemonade" and other refreshments, and $500 for decorations on the city hall. These decorations will comprise festoons of electric lights, and the wiring will be of a permanent character, for use at other conventions. Belle Isle Park will also be decorated with innumerable electric lights in Chinese lanterns. The entertainment estimates are based on cost prices and an attendance of 5,000.

In a hole in the stone retaining wall of a lawn at the northwest corner of Prospect avenue and Independence boulevard, Kansas City, Mo., lives an unusually large and well-fed toad, as we are informed by the Kansas City "Star." "An electric arc light hangs over the corner, and at night it attracts myriads of bugs and flies. It is then that the toad leaves his hole and hops out across the granitoid walk to where the insects, blinded by the light, fall upon the pavement and crawl around. The toad sits, his eyes sparkling in the electric light like beads of jet, till a beetle or a moth falls near him, and then he hops cautiously near to it. His long, red tongue shoots out with the quickness of a flash and the insect disappears down his throat. It takes a good many bugs to make a full meal for this toad, and often he is on the pavement for more than an hour. The toad is there every night and passers by stop to watch him. He keeps out of the way of pedestrians, and when he goes back to his crevice in the stone wall he moves lazily and with short, self-satisfied hops."

RECENT COMPANY ELECTIONS.

Eckington & Soldiers' Home Railway Company, Washington, D. C.—President, O. T. Crosby, president of the Potomac Electric Power Company; secretary, Dana Stevens; additional directors: H. P. Scott, of Wilmington, Del; Thomas J. Haywood, H. A. Parr, Robert Carswell, R. C. Davidson and D. M. Newbold, of Baltimore, and W. K. Schoepf, of Washington, the present receiver of the company.

Franklin Electric Company, Chambersburg, Pa.—President, S. Z. Hawbecker; vice-president, W. Rush Gillan; secretary, G. W. Klee; treasurer, M. L. Ritchey; directors: Hon. W. Rush Gillan, F. B. Shumaker, John G. Orr, G. W. Britsch, S. Z. Hawbecker, G. W. Klee, Van T. Haulman.

Springfield Electric Railway Company, Springfield, Vt.—President, Adna Brown; vice-president and general manager, E. C. Crosby; clerk and treasurer, A. J. Crosby; directors: the officers and M. A. Coolidge, F. E. Coolidge and C. W. Wyman.

Sandusky, Milan & Norwalk Electric Railway Company, Sandusky, O.—President, George H. De Witt; vice-president, Henry Kelley; secretary, J. D. Parker; treasurer, A. W. Prout; directors: G. H. DeWitt, W. H. Gilcher, Jacob Kuebeler, John Whitworth, L. W. Hull, Sandusky; J. D. Parker, T. B. Taylor, Perkins; Valentine Fries, Henry Kelley, J. W. Stoakes, R. Turner, Milan; B. C. Tabor, Norwalk.

COMMERCIAL PARAGRAPHS.

The Babcock & Wilcox Company, New York, report sales for first six months of 1898 in excess of first ten months of 1897. A notable order which they are now filling is that for the 96th street power station of the Metropolitan Street Railway Company, New York. This order for 15,000 HP. Wrought Steel Type Boilers is the largest stationary boiler order ever placed. Previous sales to the Metropolitan Street Railway Company amount to 7,500 HP. Sales to electrical industries in 1898 to this date aggregate 37,511 HP.

INCORPORATIONS.

The Paris Light & Power Company, Paris, Tex.—to manufacture and sell gas and electricity for light, power and heat. Capital stock, $60,000. Incorporators: T. J. Record, J. A. Porter, D. H Scott, J. D. Crook and B. J. Baldwin.

The Ottumwa Electric & Steam Company, Ottumwa, Ia. Capital stock, $225,000. President, J. H. Merrill; secretary, J. B. Sax.

The Central Electric Railway Company, Kansas City, Mo.—to construct and operate about fifty miles of street railway in and about Kansas City. Capital stock, $100,000. Directors: Samuel M Jarvis and Roland M. Conklin of New York City, William C. Skarritt, Edmund G. Vaughan, Frank S. Graves, William M. Reid and Edwin S. Yeomans of Kansas City.

The Adams-Bagnall Electric Company of Grand Rapids, Mich., has certified to an increase of capital stock to $225,000.

The Lamar Electric Light Company, Lamar, Col.—to furnish electric lights and power for the town of Lamar. Incorporators: A. C. Bent, M. Stram and J. W. Bent.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

ELECTRICAL PATENT RECORD.

Letters Patent Issued July 5, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

606,663. Electric Railway. John C. Henry, Denver, Col. Filed March 28, 1898.

606,664. Electric Railway. John C. Henry, Denver, Col. Filed April 7, 1898.

606,711. Trolley-Head. Charles Grover, Kansas City, Mo. Filed Nov. 13, 1897.

606,825. Contact Device for Electric Railways. Charles A. Terry, New York City, and Harry P. Davis, Pittsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company, Pittsburg, Pa. Filed March 2, 1896.

606,826. Current-Collecting Apparatus for Electric Railways. Charles A. Terry, New York City, and Harry P. Davis, Pittsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company, Pittsburg, Pa. Filed April 6, 1896.

606,827. Overhead Construction for Electric Railways. Charles A. Terry, New York City, and Harry P. Davis, Pittsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company, Pittsburg, Pa. Filed June 10, 1896.

606,828. Traveling Contact Device for Electric Railways. George Westinghouse, Pittsburg, Pa. Filed April 6, 1896. Renewed March 16, 1897.

606,917. Electric Brake. Harry P. Davis, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed Oct. 22, 1897.

606,990. Electric Railway. John C. Henry, Denver, Col. Filed April 18, 1898.

606,991. Electric Railway. John C. Henry, Denver, Col. Filed April 25, 1898.

606,679. Car-Fender. Otto W. Norling, Brooklyn, N. Y. Filed Oct. 19, 1897.

606,965. Car-Fender Supporting Means. Huibert Grootenboer, Paterson, N. J. Filed April 25, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

606,746. Electric-Light Switch. Frederic L. Temple, St. John, Canada. Filed Oct. 7, 1897.

606,939. Switch for Arc-Lamps. Charles A. Pfluger, Chicago, Ill. Filed Dec. 21, 1896.

ELECTRICAL MACHINERY AND APPARATUS.

606,646. Rheostat. Harry B. Cutter, Philadelphia, Pa., assignor to the Cutter Electrical & Manufacturing Company of New Jersey. Filed June 22, 1897.

606,761. Method of and Apparatus for Generating Alternating Currents. Maurice Hutin and Maurice Leblanc, Paris, France, assignors to the Societe Anonyme pour la Transmission de la Force par l'Electricite, same place. Filed March 13, 1894.

606,762. Alternating Current Dynamo. Maurice Hutin and Maurice Leblanc, Paris, France, assignors to the Societe Anonyme pour la Transmission de la Force par l'Electricite, same place. Filed April 19, 1895.

606,769. Electric Heater or Rheostat. Richard Van Renselaer Sill, New York City, assignor of three-fourths to Timothy Cohalan and George N. Chase, same place, and Daniel F. Cohalan, Jersey City, N. J. Filed May 24, 1897.

606,792. Electric Radiator. Frederick W. Quidas, Mount Washington, Md., assignor of one-half to Edward A. Griffith, Baltimore, Md. Filed July 22, 1897.

606,795. Electric Meter. William Stanley, Pittsfield, and Frederick Darlington, Great Barrington, Mass., assignors to the Stanley Instrument Company of Massachusetts. Filed Jan. 13, 1898.

606,819. Contact Device for Electrically Propelled Vehicles. Harry P. Davis, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company, same place. Filed April 6, 1896. Renewed March 16, 1897.

606,863. Alternating-Current Dynamo. Ludwig Gutmann, Peoria, Ill. Filed Dec. 4, 1897.

606,884. Electric Snap Switch. Alfred F. Wood, Philadelphia, Pa., assignor of one-half to John R. Edwards, same place. Filed Oct. 8, 1897.

606,954. Lightning-Arrester. William E. Athearn, Brooklyn, N.Y. Filed Aug. 9, 1897.

TELEPHONE AND TELEGRAPH APPARATUS.

606,658. Machine for Punching Telegraph Paper. Godfrey M. Gibson, Chumleigh, England. Filed July 26, 1897.

606,764. Telephone-Exchange. Frank A. Lundquist, Chicago, Ill., assignor of two-thirds to John Anderson, Salina, and Gustaf A. Anderson, Lindsborg, Kan. Filed May 19, 1897.

606,803. Telephone System. Burton R. Dodge, Post Mill Village, Vt. Filed June 17, 1897.

606,832. Telephonic Transmitter. Thomas F. Ahearn, Detroit, Mich. Filed June 19, 1897.

606,865. Police Patrol System. Orlando W. Hart, Fall River, Mass. Filed Aug. 3, 1897.

606,912. Means for Preventing Disturbances in Telephonic Circuits. Otto T. Blathy and Koloman de Kando, Buda-Pesth, Austria-Hungary. Filed April 27, 1897.

MISCELLANEOUS.

606,830. Insulator. Ben Willard, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed April 18, 1898.

606,887. Electric Extraction of Poisons. John B. Campbell, Cincinnati, O. Filed Oct. 5, 1896.

606,921. Composition of Matter for Electric Heaters. George B. Fraley, Philadelphia, Pa., assignor, by mesne assignments, to Oscar A. Fow and David W. Van Tine, same place. Filed Aug. 12, 1897.

606,981. Process of and Apparatus for Decomposing Solid Substances. William S. Romme, New Rochelle, N. Y. Filed Dec. 18, 1896. Renewed Oct. 26, 1897.

RE-ISSUES.

11,676. Storage or Secondary Battery. Ralph Ashley, Port Republic, N. J., assignor, by direct and mesne assignments, to the Guarantor Electric Company, Camden, N. J. Filed April 9, 1898. Original No. 594,313, dated Nov. 23, 1897.

DESIGNS.

28,981. Cap for Insulators. Ben Willard, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed April 23, 1898.

28,984. Switch-Contact. Monroe Guett, Hartford, Conn. Filed May 23, 1898.

28,997. Transformer-Casing. James W. Packard and Henry W. Wiswell, Warren, O. Filed May 20, 1898.

TELEPHONE AND TELEGRAPH.

The Independent Telephone Movement.

The Boston *News Bureau* gives the following statement relative to the independent telephone movement in the West, which it credits to Vice-President and General Manager Charles Webster of the Western Electric Telephone Company, who was in Boston last week:

"The Western Electric Telephone system is composed of 3,000 miles of toll lines in operation in Minnesota, Iowa and North and South Dakota. We are putting in copper metallic circuits on all of our trunk lines. We are now building a line from St. Paul to Duluth, Sioux Falls, La Crosse, etc., 1,000 miles in length, and by January 1, 1899, we expect to have 5,000 miles of wire in operation.

"Our system is composed of the Union Electric Telephone Company, capital $100,000; Minnesota Central Telephone Company, capital $100,000; Western Electric Telephone Company, capital $100,000; Western Minnesota Telephone Company, capital $30,000, and Southern Minnesota Telephone Company, capital $30,000.

"After a year's fight independent companies have obtained franchises in St. Paul and Minneapolis, where the Northwestern Telephone Exchange Company, a sub-company of the Erie Telephone Company, operates. In Minneapolis we have organized the Minnesota Mutual Telephone & Telegraph Company, with $300,000 capital, and the company already has between 5,000 and 6,000 subscribers on five-year contracts, on the basis of $48 per year for long distance instruments. The Northwestern Company charges $6 per month for business telephones and $10 per month for long distance telephones. The new company will not start for a year at least. It is now putting its wires underground.

"The independent telephone movement in the West has assumed large proportions. In St. Louis the Kinloch Telephone Company will soon have one of the finest plants in the country in operation. The new company starts with 6,000 subscribers.

"Our company has the largest independent system in the country, although the oldest of our six companies is but three years old.

"Net earnings have been put back into the property, but the companies are now earning from 8 to 10 per cent. We will begin the payment of dividends at the rate of 4 per cent. on the stock of the Western Minnesota and Minnesota Central companies next month."

The sender of a telegraph despatch, it seems, and not the company, must pay for the tax stamp. In reply to the direct question whether a telegraph company or the sender of a message was expected to pay the stamp tax, Commissioner Scott has ruled as follows: "Section 7 of the war revenue law makes it a misdemeanor for any person to make, sign or issue any instrument, document, or paper requiring stamps without having thereupon the stamp to denote the tax." "This ruling," says W. H. Baker, vice-president and general manager of the Postal Telegraph Company, "is in accordance with previous rulings of the Department upon which our action and instructions were based. The law furthermore makes it obligatory upon telegraph companies to see that these stamps are affixed, and the Government will hold responsible any person failing to comply, and will hold us responsible if we permit messages to be transmitted without stamps." It has been decided that messages over leased telegraph wires, when sent by the lessees, do not require stamp taxes.

The American Long Distance Telephone and Telegraph Company has succeeded in securing right of way for its lines through the principal counties and cities of Southern Illinois, and has begun the erection of its poles and wires. The main line will run from Evansville to St. Louis and a branch will extend from Mascoutah to Cairo. The line between Mount Vernon, Nashville and Mascoutah is already completed and offices will be located immediately. The Southern Illinois district headquarters are at present at Chicago, but it is understood that as soon as the lines are completed the headquarters will be located in St. Louis.

"Among influential leaders of the Trades League," says the Philadelphia *Stockholder*, "there is a project on foot to unite all the independent concerns outside the Bell Company in a strong organization to start a life-or-death contest with the Bell Company in Philadelphia, making this the battleground upon which will be fought out once for all the conflicts which have been raging in a sporadic way for several years past throughout the country."

Under the District appropriation bill, which has now become a law, "it shall be unlawful for any person or any telephone company doing business in the District of Columbia to charge or receive more than $50 per annum for the use of a telephone on a separate wire; $40 for each telephone, there being not more than two on a wire; $30 for each telephone, there being not more than three on a wire, and $25 for each telephone, there being four or more on the same wire." It is understood that the Chesapeake & Potomac Telephone Company will appeal to the District courts to declare the law invalid.

A complete telephone system now connects all the committee rooms of the U. S. House of Representatives. The switchboard is in the long corridor of the basement and 'phones have been placed in forty-nine different committee rooms. The instruments are of the long-distance variety, so that one can converse from almost any room in the Capitol with any other room, with all telephone subscribers in Washington, or with subscribers at distant points. A similar system has been in operation at the Senate end for several months.

Florence, S. C., will soon be connected by telephone with the extreme southeastern portion of the county, a distance of 42 miles. This arrangement is now being perfected, and in a few days Florence, Claussens, Hyman, Forrestville, Savage, Allison and several other small places along the route will be within speaking distance of each other. The system of 'phones to be used will be the "Imperial," which is manufactured by the Mason Telephone Company of Sumter, S. C.

The long-distance telephone line is being extended to Douglas from Nicholls, Ga., on the Waycross Air-Line. The line is being built along the right of way of the Waycross Air-Line extension. Douglas will soon be communicating with Waycross, Brunswick, Thomasville, Tifton and intermediate points by telephone.

The Pennsylvania Electric Company was awarded the contract for furnishing 155 transmitters to be used in the new telephone service which the Police Department of Buffalo, N. Y., is to construct, the company's bid being $3.77 each. The Wilhelm Telephone Company of Buffalo was awarded the contract for furnishing 155 receivers at $2.25 each, 12 adjustable desk sets at $3.50 each, and 18 desk sets for the station-houses at $8 each.

The Southwestern Telephone Company has commenced the building of lines from Texarkana, Ark., to Pine Bluff, Ark. The course of their construction is along the right-of-way of the Cotton Belt Railroad and all towns situated on this thoroughfare will be given a telephone office.

The officers of the Signal Corps with Shafter's army are keeping pace fully in establishing telephonic communication in every direction where the army makes its move. In the captured Spanish intrenchments at Santiago telephones were found in perfect trim, showing that in means of communication at least the Spanish army is quite up to date.

A movement is on at Richmond, Ind., for an independent telephone exchange to compete with the Central Union Company. Robert Cokefair, of Anderson, is promulgating the scheme. A toll station will soon be established at Richmond by the Citizens' Telephone Company.

The Home Telephone Company is booked to occupy the upper stories of a new terminal depot to be built for the suburban electric roads at Cleveland, O. The Home Company has passed into the control of the Everett syndicate, which will erect the building.

The experiment of placing telephones in country farm houses is being tried with success in farming sections of Minnesota. 'Phones have been placed in several centrally located farm houses for the use of the residents and their neighbors.

A telephone company was organized at Wynnewood, I. T., on the 2d inst., whose purpose is to build telephone lines to Roff, McGee, Center, Brady and Foster, giving telephone connections to all country towns of importance.

A Detroit paper states that on September 1 the Detroit Telephone Switchboard & Construction Company will begin work on a 5,000 telephone exchange in New Orleans.

A police telephone system will probably be established in Binghamton, N. Y. The chief officials of the city are considering the matter.

The authorities at Washington have decided that messages over private wires do not require stamps.

New Companies Incorporated.

The Oklahoma Telephone Company, Guthrie, Okl. Capital stock, $100,000.

The Detroit Switchboard & Telephone Construction Company has certified to an increase of capital stock from $100,000 to $250,000.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

In this column, June 15, appeared a paragraph containing the statement referred to in the subjoined note. It was based upon an item in the financial columns of a Philadelphia paper and we had no reason to doubt its authenticity:

"Streatham Hill, London, June 23, 1898.—Your issue of June 15 states that the British Electrozone Company paid 25 per cent. in dividends upon a capital of $5,000,000 in 1897. May I inform your readers that 'Burdett's Official Intelligence' contains no information concerning the company (a bad sign), and that the company is now in course of voluntary liquidation.—JOHN B. C. KERSHAW."

Late quotations for copper are: Electrolytic, 11⅛@11⅜c.; Lıke, 11⅞c.; casting, 11⅛@11⅛c.

The Columbus (O.) Street Railway Company has declared a dividend of 1 per cent., payable August 1.

The plant of the Cincinnati Electric Light Company, according to a press dispatch, was destroyed by fire on the 8th inst. Loss over $100,000.

The Brooklyn (N. Y.) City Railroad Company has declared a dividend of 2½ per cent., payable July 15 to stock of record July 9. Books reopen July 16.

The stockholders of the New England Telegraph & Telephone Company on recommendation of the directors have voted to increase the capital stock of the corporation from $12,000,000 to $15,000,000.

At the last meeting of the directors of the United Securities Company, Boston, Arthur Perry, vice-president and general manager, and Allston Burr, treasurer, resigned their respective positions, the resignations to take effect September 1 next.

The gross passenger receipts of the North Chicago Street Railway Company for June were $253,569, against $238,779 last year, an increase of $14,790. For six months the earnings have been $1,407,942, against $1,326,155 last year, an increase of $81,787.

The Boston "News Bureau" asserts that the statement that President C. A. Coffin of the General Electric Company had been elected a member of the General Electric preferred stockholders' committee is erroneous. Nobody has as yet been appointed on the committee to succeed Mr. Samuel Carr, resigned.

President H. C. Payne of the Milwaukee Street Railway Company announces that the company will spend $1,000,000 on improvements this year. The line will be extended to the Milwaukee suburbs and resorts over a radius of 30 miles. A new power house is being erected for the Wauwatosa line.

In regard to equipping the Manhattan Elevated road of New York with electricity, Mr. Russell Sage says the subject is being considered, but will not be decided until Mr. Gould's return. He pronounced the statement that the General Electric Company had secured the contract untrue.

The City Passenger Railway Company of Baltimore have decided to issue $1,000,000 additional capital stock. Stockholders will be given the privilege of subscribing to the new stock, par $25, at $50 a share, at the rate of two shares for each five now owned. This will increase the stock debt of the company to $3,500,000.

The Philadelphia "Times" says: "The latest report about the North American Company is that a strong party (not Mr. Villard) wants to get control, so as to use the liberal charter for a parent company for surface railroad lines, including some New York and Brooklyn systems."

The directors of the Providence & Taunton Street Railway Company have petitioned the Railroad Commissioners for permission to increase the capital stock of the company from $160,000 to $175,000. The Commissioners will give a hearing to the parties in interest at their office, 20 Beacon street, Boston, on the 14th inst.

The Citizens' Street Railroad Company of Indianapolis has filed a mortgage extending to June, 1900. It was for the payment of $700,000 of bonds held by the Illinois Trust & Savings Company and S. J. Fletcher, trustees. The original issue of the bonds was in 1892 and they were made payable in four years. In 1896 they were extended until 1898. Of the amount $100,000 has been paid.

The annual meeting of the Welsbach Light Company was held at Gloucester, N. J., on Friday last, William Findlay Brown presiding. The annual report shows: Net earnings, $475,207, increase $12,130; dividends, $412,745; depreciation, $14,191, decrease $2,224; balance, $48,260, increase $11,365; total undivided profit, $149,852, increase $47,260; charged off patent account, $30,387; surplus, $119,465; increase $17,873.

The Louisville "Post" of the 4th inst. says: "The reorganization of the New Orleans Traction Company has been postponed for another six months. This is because the company has just paid its semi-annual dividend of 2½ per cent. on the $3,000,000 of bonds. The reorganization committee, which is composed mainly of Louisville capitalists, endeavored to have the company default on the July interest in order to push the work of reorganization, but, as stated above, a failure was made of this."

A report is in circulation that the new Kings County Electric Light & Power Company is negotiating for the acquisition of the property and franchises of the Edison Electric Illuminating Company of Brooklyn, N. Y. If the deal is consummated, it will place the Kings County Company in possession of almost the complete electric lighting field of the Borough of Brooklyn. Among those said to be interested in the Kings County Company are Roswell P. Flower, Anthony N. Brady, William Berri, Seth L. Keeney and Felix Campbell, president of the People's Trust Company.

The foreign demand for electrical equipment for railroads and power stations, according to parties in a position to know, will be more active in about two or three months. Estimating on new work is extensively under way to a greater extent with electrical engineering concerns having branch offices in London and Hamburg, where the majority of large foreign contracts are usually closed. As American manufacturers of such equipments are successfully competing in every part of the world, it is more than likely that a good share of the work now being estimated for will be secured by our manufacturers.

The Quebec, Charlevoix & Montmorency Railway Company has taken over the electric railway system of the Quebec District Railway Company. The bonds of the amalgamated concerns, amounting to $1,500,000, were sold to Hansen Bros. of Montreal, who have paid for some $1,150,000 of the issue. The remaining $350,000 of the bonds are to be used for further extending the present city electrical system, and electrifying the steam system of the Quebec, Montmorency & Charlevoix Railway, so that in the near future pilgrims and others will be able to visit the shrine of St. Anne de Beaupre by electric cars.

The directors of the Kings County Traction Company will sell at public auction, at the New York real estate salesroom, 111 Broadway, New York, on July 14 the assets of the company as follows: 39,987 shares of the capital stock of the Atlantic Avenue Railroad Company of Brooklyn, and options upon the remaining thirteen shares of said capital stock, and also options upon nine shares of the capital stock of the Brooklyn, Bath & West End Railroad Company. All of these shares and options are now deposited with the Central Trust Company, subject to the terms of an option agreement, dated April 4, 1898, executed between the Nassau Electric Railroad and the Brooklyn Traction Company, and are to be sold subject thereto. The sale is preparatory to the winding up of the company's affairs. When it is completed the Nassau Company's new stock and bonds will probably be ready for listing on the exchange.

ELECTRICITY.

Vol. XV. NEW YORK, JULY 20, 1898. No. 2.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 1081 Cortlandt.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	2.00
FOREIGN COUNTRIES,	4.50
SINGLE COPIES,	10 cents

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

A New Form of Range-Finder.

At the present day the aiming of a sea-coast gun at a vessel is an exact science. In the days of smooth-bore, cast-iron guns immense quantities of metal were fired at long range more or less by guesswork, in the hope that at least a small portion of it might hit the target. Since the introduction of smokeless powder all this has been changed. The range and the direction of the target are now computed by delicate electrical instruments known as range-finders, which make correct allowances for the rise and fall of the tide, the direction and force of the wind, the curvature of the earth and many other seemingly unimportant variations. An entire fleet of naval vessels may now be destroyed by the guns of batteries whose commanders fire without seeing a single ship, but who are informed over a telephone or telegraph wire of the exact position of every vessel of the fleet. Range-finding, as is now generally known, is merely an application of an elementary principle of trigonometry applied to surveying. The range-finder which has up to the present been generally used by the Government is that invented by Lieut. Bradley A. Fiske, and which gives the distance of an object from a ship by the aid of an electric current working through two rheostats and a Wheatstone bridge. Observers at the bow and stern of a ship follow the target with telescopes mounted on pivots. The turning of the telescopes varies the resistance of the rheostats and the changes in the intensity of current move a range indicator in the Wheatstone bridge. Of late, however, a new form of range-finder has been extensively adopted for coast service, the Government having purchased some two hundred of these instruments. These latter, known as the Lewis depression range-finders, calculate distance by a method of triangulation, the height of the instrument above sea level forming the base of a triangle. All the depression finders are so constructed that the movement of the telescope as the observer follows the target moves the range indicator about a graduated scale, and thus it is only necessary to glance at the scale to know the range. The advantages claimed for the depression finder are that but one observation station is needed, and in the event of an instrument through any mishap giving out, a reserve instrument may quickly be set up in its place. The Lewis depression position finder is generally believed by army officers to be the most accurate instrument of the kind yet devised. It is claimed to have a maximum error not exceeding 1 per cent. up to 10,000 yards.

The instrument consists of a polished iron table some four feet in diameter, which rests upon an iron column and supports a pivoted traversing arm carrying all the other parts of the instrument. In front the arm has an upward curve which acts as a support for the horizontal axis of a forty-inch telescope magnifying twenty-five diameters. The telescope may be raised and lowered by a crank operating a carefully adjusted mechanism at the eye end. It is swung around in azimuth by a larger crank turning the traversing arm about on its pivot.

By revolving the traversing arm the friction roller of the azimuth-measuring device is turned. Each revolution of the roller corresponds to a given number of degrees of the azimuth. This mechanism is located behind a square sheet of metal, placed vertically just under the eye end of the telescope. Through one opening in the sheet the operator reads the degrees and through another the minutes of azimuth. The screw by which the telescope is raised and lowered meshes with the gear of a horizontal range wheel, one foot in diameter, projecting from under the table below the azimuth reader. There are 600 teeth on the circumference of this wheel. A white sheet of celluloid, one-sixteenth of an inch in thickness, is set into the wheel and graduated about its circumference in black. The range of an enemy's vessel entering a harbor would be taken every ten seconds by means of an electric clock which strikes the intervals. As it is essential that the Lewis depression finder should be made perfectly level before being used, so that the traversing arm may be swung about without changing its horizontal position, this form of instrument cannot be adopted on shipboard owing to the constant movement of the vessel, and the Fiske range-finder will undoubtedly be continued in use on vessels of the navy.

* * *

The Paris Exposition of 1900.

From all accounts American manufacturers of electrical machinery will have an opportunity of furnishing the Paris Exposition of 1900 with electrical machinery to the value of $1,000,000, in spite of the rumor which was current not long ago that owing to the stand the French nation had taken on the war question this country would refuse to be represented at the Fair. Mr. Louis M. Hamburger, who some time ago was appointed a special commissioner to visit Paris and look over the ground, on his return is credited with having made the statement that the French Government evidently desired to cultivate the friendship of America, and that while Germany and Russia had each appropriated $1,250,000 to defray the expenses of a display at the Exposition, this country had as yet made no appropriation or even appointed a permanent commission, yet in spite of this fact the French Exposition authorities had defined the space America would

have. The New York *Times* credits Mr. Hamburger with the following statements which would seem to give a very clear idea of the situation :

"Before leaving Paris, I saw statements in American papers that Americans in Paris were subjected to annoyance there; that they were elbowed off the sidewalks, etc. I saw nothing of that myself. I met with no evidences of hostility and found no well-informed person that doubted the ultimate success of the American arms. The money spent by the Government for the Exposition will be in the nature of an advertisement for American goods, and a larger foreign market for our goods will be most agreeable after the drain upon our resources inflicted by the war. The concessions obtained from the Exposition authorities in the interest of American electrical machinery, and a definite guarantee of display space such as has been granted to no other country, are good evidences of French friendship with us."

That America should be well represented in the electrical line at the Exposition of 1900 goes without saying, and there is also not the slightest doubt but what a fine exhibit of electrical apparatus would greatly tend to increase our exports to Europe as well as to South America, as Paris is still the great center where converge the commercial and financial interests of the Latin races.

* * *

The Electric Arc. The electric current, as is well known, has already been extensively employed in welding the ends of trolley rails, thus making them continuous with a view to decreasing the resistance of the return circuit and preventing to some extent electrolysis. The rails are made continuous usually by what is commonly known as a portable electric welding car. The latter is provided with the necessary electrical equipment, and may be moved from point to point along the track. On reaching a rail joint which it is desired to weld, an arm is let down and attached to the rails at that point in such a manner that when an electric current is turned on an arc is formed between the rail ends, thus fusing the molecules of steel together. A car of this description has been a familiar sight in Brooklyn, where miles of rail joints have been welded by this method. A similar line of work is also being carried on by a firm in Western Pennsylvania where track junctions or frogs for railway crossings are electrically welded. Recently, however, new uses have been found for the electric arc which, in view of our war with Spain, are exceedingly important. The welding process has lately been adopted by the Government in the manufacture of shells for both the navy and army. Heretofore the projectiles were made of cast-iron or steel by an exceedingly costly process. Now a shell is made in two portions, the point of very high carbon steel, the base of ordinary machine steel, and the two are electrically welded together at a comparatively slight expense. The electric arc now also plays an important part in the construction of our men-of-war. A short time ago it was an extremely tedious and difficult piece of work to bore a hole in the harveyized plates which are used as an outer protective skin on the ships of our navy. These sheets of metal are on the surface almost of the hardness of glass and as hard as the steel drill which is used to perforate them. Under these conditions it will readily be seen that to bore a large number of holes in a harveyized plate by means of a drill would entail an immense amount of time and labor. This tedious process has now been done away with and the electric arc substituted. By means of a specially designed apparatus, a hole may be fused through this hard steel surface almost in an instant.

Another comparatively recent application of the arc is the closing of blow-holes in castings. This is accomplished by heating the casting red hot and connecting it to one pole of a dynamo, a metal bar being connected to the other pole. The bar on being held to the blow-hole causes an arc to be formed which fuses the adjacent parts, thus closing up the blowhole. The electric arc is also quite extensively used at the present time for fusing together the ironwork of high buildings, and is also used to some extent by the larger manufacturers in joining the hard and soft parts of steel and iron tools. In short, at the present time there would seem to be scarcely a department of metal-working to which the electric welding process cannot be applied with a saving of both time and money.

Under the Searchlight.

Notes and Comments on Various Topics.

The Brooklyn Electric Light "Combine."

The fact that the Kings County Electric Light & Power Company had absorbed the Edison Electric Illuminating Company of Brooklyn was made public on the 16th inst. by the following circular letter :

Brooklyn, N.Y., July 15, 1898.

Mr. George Foster Peabody, of the board of directors of the Edison Electric Illuminating Company of Brooklyn, acting in consultation with the officers, has to-day closed, in behalf of stockholding interests represented by his firm, and equally for all others, a proposed sale of the stock of this company to the Kings County Electric Light & Power Company, upon terms which the members of the board of directors unite in thinking for the permanent advantage of the stockholders. Counsel are preparing the papers in detail to carry out the agreement, provided it shall be accepted by two thirds of the stockholders.

As soon as these details are in proper shape the matter will be fully submitted to each stockholder of record. The result to the stockholders will be in substance that the right to subscribe to 25 per cent. additional stock, at par, will be secured to them, and that for the whole amount of stock they will then be offered par in ninety-nine-year 6 per cents. Purchase money mortgage bonds to be secured by the deposit of the Edison stock so sold, and additionally by a junior mortgage of the Kings County Company upon its property, and further by a deposit of a guarantee fund of $1,000,000.

This prompt preliminary notice is sent at once, and full information will be sent promptly upon completion of the papers during August ETHAN ALLEN DOTY.

That the amalgamation of these two companies has at last actually been consummated does not surprise us in the least, as ELECTRICITY more than a year ago predicted that such a consolidation would take place. The stockholders of the Edison Electric Illuminating Company may find that after all it is simply a case of "out of the frying-pan into the fire." When will this constant manipulation of electric securities cease?

* * *

An Engineer's Heroism.

A WILD Indian, says the Macon, Ga., *Telegraph*, is something awful, but a wild engine is about as terrifying a contrivance as a man could think of. Imagine a huge steam giant, with power enough to run away with a freight train, tearing about in a power house, its governor strap broken, its huge arms making several hundred revolutions a second and smashing everything within reach. Such was the scene in the central station of the Macon Consolidated Street Railroad Company a few days ago. The engine was a stationary one of great power and was one of those used to generate electricity for the street car company. When its governor strap broke, and before the engineer, W. M. Brevard, could reach it, the governor had blown wide open and the increased speed had thrown it on its side. In spite of the escaping steam, mud and pieces of iron which filled the air, Brevard, at the risk of his life, seized the governor and shut off the steam. As it happened, only five or six hundred dollars' damage was done and the engine will probably be able to go back to work in a few days.

* * *

ALTHOUGH happily we do not number among our readers, as far as heard from, any person addicted to the use of intoxicating beverages to such an extent as to render him liable to optical delusions of an ophidian nature, some of them possibly may have acquaintances outside of our clientage whose minds they can relieve by communicating to them the following intelligence which we reproduce from a trustworthy source : "In view of the fact that a large majority of the visual hallucinations accompanying cases of delirium tremens consists of the appearance of snakes and worms, a series of examinations with the ophthalmoscope were recently made and brought to light some interesting facts. In sixteen cases examined there was found in every case an abnormal condition of the blood vessels of the retina. Instead of having their usual appearance and being pale and but slightly visible, they were dark with congested blood. Normally, these small blood vessels are so small and semi transparent that they are not projected into the field of vision, but in the case of this disease they assume great prominence, and their movements seem like the twistings of snakes."

* * *

AFTER a recent trolley collision a Scotchman was extricated from the wreckage by a companion who had escaped unhurt.

"Never mind, Sandy," his rescuer remarked; "it's nothing serious and you'll get damages for it."

"Damages!" roared Sandy. "Hae I no had enough. Guid sakes, it's repairs I'm seekin' noo."

* * *

IT must be a rather ludicrous sight to see a man shut in a telephone booth and making vain efforts to get out. Such a scene recently took place in a certain cigar store in Brooklyn, and the hurried business man was obliged to resign himself to his fate until a policeman secured a carpenter who took down the booth and thus restored the captive to liberty.

* * *

MAJOR HENRY M. ADAMS, who has charge of the mine fields in New York harbor, has received from Brig.-Gen. John M. Wilson, Chief of Engineers, a letter of instructions in reference to removing the mines in the harbor. Under these instructions Major Adams is authorized to remove the mines in any channels under his supervision where the interests of commerce demand the removal. He is directed, however, to leave in position the cables, junction boxes, anchors and casemate appliances, so that mines may be planted immediately upon telegraphic instructions from Washington.

* * *

An Electric Love Alarm.

The ingenious father of an estimable young lady in Sheffield, says *Pearson's Weekly*, recently rigged up a clever contrivance by which he discouraged a certain young man who had been accustomed to make love to his daughter. The old gentleman recently caught the young man and girl rather close together on the sofa. He read the girl a lecture and made her promise not to let the young man sit beside her on the sofa again. He was suspicious, and decided not to trust the girl's promise, so he called in an electrician to carry out a little scheme of his. A contact plate was fitted just under the cushion of the sofa and another to the bottom of the frame in such a way that when the weight of two persons bore down upon the top plate it would touch the other and close the circuit. Wires were run from the plate to the old man's bedroom, where as soon as the circuit was closed a small bell would ring. All this was done without the knowledge of the girl. The next night the young man called again, and everything was as it should be until the old folks retired about 10 o'clock. About half an hour later the bell upstairs rang furiously. The old man sneaked down stairs and caught the lovers snuggling very close together on the sofa. The young man escaped with his life, fortunately, but the poor girl is locked up on a diet of bread and water.

ON THE NECESSITY FOR UNIFORMITY IN PLANT AND APPARATUS.*

BY C. H. WORDINGHAM, A.M.I.C.E.,
City Electrical Engineer, Manchester, Eng.

The principles enunciated by Dr. John Hopkinson in his classical paper on the cost of electric supply† are now fully appreciated by the majority of supply engineers, municipal and other, but it is doubtful whether they recognize that their own field of labor is but one very small, indeed insignificant, plot in the wide area to which these principles apply.

Manufacturers of all engineering products have to face the same problem, viz., the production of articles the cost of which is made up of two items, one independent of the quantity sold, the other practically proportional to that quantity.

In the case of manufacturers, the standing charges comprise the establishment of the works, i. e., the cost of land, buildings, engine power, machinery and tools, drawing office staff, patterns, etc.; the establishment of offices, and in many cases of show-rooms, with staff of clerks, travelers, etc.; the holding of a stock to supply the demand without delay; while to these standing expenses must be added the salaries of a number of engineers, managers, etc., who must be ready to design the articles manufactured, and who must be kept up to date in the latest practice, often at great cost.

The running expenses are wages for labor, skilled and unskilled, fuel, oil, etc., for running the works, repairs to machine and other tools, raw material.

Probably no better example of high cost could be taken than the manufacture of submarine cables. In this case both items are greatly exaggerated. A large amount of very expensive machinery occupying great space and extensive buildings has to be provided and kept in good order, to be used perhaps once in the year, and when it is required it frequently happens that the work is of an urgent nature, and manufacturing has to be kept going day and night for a few weeks, necessitating overtime and high rates of wages, together with excessive wear and tear of plant, while the cost is still further augmented by the fact that the cable is probably of a special size and design.

Now let us examine into the means by which the cost of manufacture may be reduced. Assuming that all that is possible has been done to economize by the choice of a site where land is cheap, by suppression of superfluous cost in the erection of buildings, by skilful design to avoid unnecessary handling of goods, by the absence of display in offices, etc., what remains to enable the manufacturer to reduce his cost? One thing pre-eminently, restriction of the number of types and sizes of the articles produced. To produce say a dynamo, machine or an engine, a number of calculations have to be made, then a series of drawings must be prepared, next the patterns, and finally the tools. All this means large expense, and if only one article is made, the whole cost has to be charged to that article, and this standing cost may completely swamp by comparison the cost for material and labor. Whereas, if a thousand such articles were required, the fixed cost, being divided amongst them all, would be only one-thousandth part of what it was in the case of one. By limiting the number of patterns, it becomes possible to devote more time and attention to perfecting the design and the tools necessary for the manufacture, hence higher efficiency is gained in conjunction with reduced costs, for, though the provision of the tools requires a slight addition to the standing cost, it is quite inappreciable when divided among the number of articles sold, and there is a corresponding saving effected in labor.

The subject as a whole is a very wide one, but this paper must necessarily be confined to the particular case of electric supply stations, and the author hopes to be able to show that, even limited to this small area, the question is of great importance.

At present, every engineer in designing a station seems to think it incumbent upon him to have something different in his station to that in every other. One fixes upon some peculiar declared pressure, involving special designs for every lamp, motor, radiator, or other consuming device that is to be attached to the circuit. Another wants alternating current of special periodicity, or transformers of an unusual capacity, or in a case of some unheard of shape. Another wants extra large boilers or dynamos of a capacity different to any stock size. Another requires cables of a size necessitating strands of some odd gauge of wire. No doubt this is not wholly intentional, but arises partly from want of thought, partly from ignorance and partly, it is to be feared, from a feeling that manufacturers are a kind of inferior race, who cannot possibly know as much as the engineer, and who must do as he tells them. Now it is essential to success, both mechanically and financially, that the engineer and manufacturer should mutually strive to secure it; the manufacturer must endeavor to carry out the engineer's objects, and the engineer must subordinate the details of his scheme to the convenience of the manufacturer. No man can know everything thoroughly, and it must be admitted that a manufacturer who devotes his whole time and energy to the production of a particular class of machinery, or apparatus, must know more about that particular class than the engineer with whom it is but one item out of the many comprising his whole scheme. Only those men whose standing in the profession is assured dare to admit and recognize this, the second rate men fear that their doing so will be construed into a confession of ignorance or incompetency.

As an evidence of the want of uniformity now existing, I have made inquiries as to the practice as regards certain points, and through the courtesy of engineers running the stations have obtained the following information. The particulars relate to 109 stations, in 46 of which continuous current is employed, in 55 alternating and in 8 both alternating and continuous.

First as regards declared pressure, the following table gives the number of stations and the various pressures declared :

TABLE A.

Declared Pressures.

Declared pressures.		Continuous current.	Alternating current.
50	Volts.	—	1
50—100	"	—	2
84 - 103	"	—	1
90—100	"	1	—
100	"	8	29
100—200	"	10	10
100—105	"	1	1
102	"	—	2
102—205	"	—	2

220 — 440	"	8	—
230	"	3	—
	Total	51	58

In addition to the above, a few stations give special pressures for special reasons. One station varies its pressure according as the transformer is made by one or other of two manufacturers. Another which normally supplies at 100 volts supplies at 102 by special arrangement with a "lunatic asylum!" A third supplies at 113 volts, but naively recommends 110 volt lamps. Apparently this station is not run on the same lines as those in which the declared pressure is "102½ volts."

Incidentally, it may be remarked that the permission given by the Board of Trade to vary the declared pressure in different districts is practically never taken advantage of, while as against this, one station in defiance of all Board of Trade regulations, boldly declares a pressure of 420 volts.

The next point of importance in which the practice differs is the question of periodicity in alternating stations. The periodicities are set forth in the following table :

TABLE B.

Periodicities—Periods per Second.

3 at 10	6 at 83
7 " 50	1 " 83.5
1 " 58	1 " 83—100
6 " 60	1 " 87
1 " 67.5	1 " 87.5
1 " 74	2 " 90
3 " 75	2 " 93
1 " 75—80	17 " 100
1 " 77	1 " 125
2 " 80	

Total, 58

The size and pressure of the generators is the next point of interest. It did not appear worth while to tabulate the pressures generated in low pressure stations, as the declared pressure is a sufficient indication of the pressures used. As regards the high pressure generators however, the following table shows the pressures generated :

TABLE C.

High Pressures Generated.

Pressure. Volts.	Continuous. No. of stations.	Alternating. No. of stations.
1000	8	8
1000—1050	1	—
1400	1	—

2200	—	1
2400	—	1
2500	—	2
8000	—	1
Total	7	59

The size of generator is very important, and here again there is a most extraordinary discrepancy in the sizes employed. These are tabulated in Table D. Without entering into the number of machines, which do not very greatly affect the question, the following sizes are in use :

TABLE D.

Size of Generating Unit.

Continuous		Alternating		
KW.	KW.	KW.	KW.	KW.
10	80	20	62	150
12	88	22	66	154
15	90	23	70	160

75	1500	60	140	......

Inquiries as to whether standard sizes of mains, meters, etc., were employed, showed that in many instances such is not the case, the size being chosen haphazard according to requirements.

The above figures will serve to show the utterly chaotic state of central station practice as regards standardization in this country at the present time, and very little consideration is necessary to show that the difficulties to be coped with by manufacturers in consequence must be enormous, and that, for the reasons stated at the beginning of this paper, the price of plant and apparatus to users must be very largely augmented, without there being any corresponding additional profit to manufacturers. The additional cost is in fact pure waste, and benefits nobody.

No doubt it is inevitable, in the early stages of any industry, that there should be great diversity of practice—indeed it is desirable that things should not become stereotyped until the best has been discovered, but we have surely now arrived at a time when we can make up our minds on such subjects as

* Paper read before the Municipal Electrical Association, London, June, 1898.

† See Dr. John Hopkinson's paper on "The Cost of Electric Supply," read before the Junior Engineering Society on the 4th November, 1892.

those enumerated above, and it is of vital importance that the matter should be settled soon, for each new station that is to be built perpetuates its own set of quantities.

The most important point of all is the declared pressure, for this affects every consuming device as well as generators, or transformers if used. While it should be so fixed as to admit of as economical distribution as possible, it should not involve a loss to the consumer in wasteful resistance, or in enhanced price for lamps specially fragile or difficult to manufacture.

The author ventures to think that, taken all round, 100 volts and multiples thereof is the most convenient pressure, and the one most likely to meet with general acceptance. In the first place, it is that most largely used at the present time, and it meets the conditions named above, since two ordinary arc lamps, or one enclosed, can be made to burn steadily at 100 volts, the waste in resistance being reduced to a minimum, while for the first multiple, viz., 200 volts, there is little difficulty in obtaining single incandescent lamps. Moreover, it gives a convenient pressure across the outer conductors, a pressure suitable for tramway working, while allowing a good margin for loss on low pressure feeders, without necessitating a higher pressure at the generating station or transforming station than 500 volts, which is the limit of low pressure fixed by the Board of Trade. Incidentally, 100 volts is very convenient for mental calculations, and for meters when ampere hour instruments are employed.

In passing it may be remarked that a good deal of doubt appears to exist as to the exact meaning of the Board of Trade definition of low pressure, viz., whether 500 volts is the limit at the station or at the network end of the feeder, and an authoritative interpretation of this would be very acceptable.

Other directions in which standardization is necessary may be mentioned here, viz., the adoption of standard candle powers for incandescent lamps. It would appear that no more than four sizes below 100 candle power are really necessary. A little consideration will show that, quite apart from the question of manufacture, the limiting of the number of sizes would enormously reduce the amount of stock that has to be held, and hence a large amount of capital uselessly locked up would be set free.

The number of sizes of arc lamps might very well be reduced. Three would suffice for all ordinary purposes. If this were done, not only would the cost of production be greatly lessened, but the ease of replacement of damaged and worn-out parts, and the cheapening of carbons, together with convenience in obtaining them, would be a great gain.

As regards motors, it is probably not worth while to make anything smaller than 2 horse power, whatever it is intended to drive, except perhaps in the case of ventilating fans. The bulk of the demand will probably be for motors under 25 horse power, and three sizes between this and 2 horse power should suffice.

So long as a supply of alternating current continues to be given to consumers, the question of periodicity will affect the stations concerned nearly as greatly as does the question of declared pressure, and it is therefore as important that some definite understanding should be come to. The variation at present, as will be seen from the table, is as great as or even greater than in the case of pressure.

The question of periodicity will always be an important one, as there can be little doubt that two or three phase current will be generated in many stations in the future, though probably it will not be supplied to customers.

Next in order of importance perhaps is the size of generating unit in the station. It was recently necessary for the author to go into this matter somewhat carefully, and he was astonished to find at what an early period in the development of a central station it becomes possible and safe to employ large units. There are practically four factors governing the choice of the unit of the plant. They are—

(1) The initial capacity of the station.

(2) The probable ultimate capacity.

(3) The steps by which it is permissible to increase the capital expenditure.

(4) The percentage safe overload of the plant.

It may be mentioned here that, in the author's opinion, it is preferable to have reserve plant in the shape of machines with considerable margin of possible overload beyond maximum economical load than in the form of spare machines, for the latter are only of use in cases of actual breakdown, while, in the former case, the reserve is always ready to be called into play at a moment's notice, and there is no delay due to having to start up another machine in case of sudden demand, whether from a running machine having to be switched out or from an abrupt change in weather. Further than this, the same amount of reserve can be attained more economically.

The conditions to be fulfilled then are, that if any one machine breaks down, the remaining machine shall not be overloaded more than a definite amount, say 33 per cent., 25 per cent. or 20 per cent. If the last named figure be adopted, this means that the first installation of plant must consist of six machines of equal capacity; their size will depend on the initial capacity of the station. When extensions have to be made, the increment of plant will depend upon the increment of capital permissible. The condition that any one unit may break down without overloading the plant 20 per cent. allows of either one, two or more machines being added. The amount of increase of capital will be a minimum if only one machine be put down, but this course is open to the serious objection that it means a number of machines all differing in size after the first six, hence absence of interchangeability of plant, and an unsightly station. It would appear most convenient to increase the plant by pairs of machines, since this gives a symmetrical arrangement, allows of reduction of spare parts, and renders the machines convenient multiples of one another. Time does not admit of a particular case being worked out, but if this be done it will be seen that a large size is soon reached, and after a certain point the rule cannot be carried out, as it leads to engines of impracticable size. It then becomes necessary to add each time one or more machines of the same size. It would be a matter of great interest to learn from engine and dynamo builders what is the upper limit of size of generator.

It will thus be seen that we begin with six machines with parts interchangeable, and finish with a certain number of machines depending on the size of the station, also having the parts interchangeable, and between we have a number of machines of varying sizes. In very large stations put down on a sufficiently generous scale, all the units may be of the same size, but the author maintains that the initial number should not be less than that number which allows of one breaking down without overloading the remainder more than the specified amount, and it cannot be considered safe to put down one or two large machines to begin with, and to trust to good workmanship and design to avoid mishap.

On the above principles it should not be a difficult matter to work out a series of machines which will provide for stations of all ranks, and yet be limited in number.

Next may be considered the question of mains, both as regards the conductor and the insulation. It is greatly to be desired that only a few sizes of conductor should be decided upon. The author has endeavored to show elsewhere * that of necessity the size of main required in a given street is largely a matter of guesswork, hence it should not be a difficult matter to agree upon standard sizes that may be such that they can be made up from ordinary S. W. G. wires. If this were done, a manufacturer could afford to stock a great deal of wire, and one source of delay in delivery would be avoided.

Again, it surely should be possible to settle upon standard tests for dielectrics of different kinds for given pressures, and if this were accomplished manufacturers could stock cable actually ready for delivery. The advantage of this will be fully appreciated by central station engineers, for, instead of each one having to store for his own requirements, he would be able to order from stock, and save the expense of cable stores and their attendants, besides being able to meet unlooked for extensions at short notice, while the aggregate stock, and therefore the capital locked up, would be much less than if there were a number of separate stores.

We next come to accessories such as service cables, transformers (in the case of alternating supply), main fuses, meters, maximum recorders, meter boards, etc. Here again the ory must be standardize. Find out the best all round pattern of each, and keep to it. Have as few sizes as possible. Arrange your parts so that they shall come in if extensions take place so that the work may not have to be redone. In his own practice the author has endeavored to carry out these principles, and he has to a great extent succeeded, but it would be tedious to enter into the details.

It is of little use for one or even many individuals to standardize unless there be co-operation. It will probably be said, all admit that uniformity of plant is desirable, and you are but laboring to prove that which is evident. How do you propose that this desirable end should be achieved? The author replies that there is but one way, and that is by settling upon standards that will be acceptable to the majority of those concerned, and this can only be done by thrashing out the subject by a committee thoroughly representative of all classes interested.

This Association is representative of a section of one section only, viz., the municipal section of users of plant, and it is not therefore competent to deal with the matter by itself. The Institution of Electrical Engineers, the mother of all British electrical societies and associations, is the proper organization to which the matter should be referred, and it will doubtless be a matter of satisfaction to the members of the association to learn that our council has already approached the Institution with a view to this, and a committee has been appointed by them to thoroughly go into the question.

The recommendations of the committee cannot fail to carry great weight, and if the matter be properly taken up, uniformity will soon be secured, for it will be found that the firms not making standard plant could not compete with those that did, and users with fads would find them too expensive to indulge.

It may be thought that such a system should be international, but it is to be feared that the difficulties of securing the desired end would be such as to make it impracticable, and it would result in the matter being indefinitely postponed.

* See his paper on "The Distribution of Electrical Energy," read before the Northern Society of Electrical Engineers on the 8th November, 1897.

Electric Haulage Abroad.

It appears that the canals which intersect Ghent are now to be utilized for the first time for extensive passenger traffic. A company has recently been organized, so we are informed, with the object of running barges through these waterways by means of electricity at a very small fare. The canals in the central division of Belgium possess already a system of haulage by electric tricycles which are run on the banks alongside the canals. The canals between Ghent and Bruges and those between Ghent and Termayen are now following suit.

THE RELATIONS BETWEEN THE PURCHASER, THE ENGINEER AND THE MANUFACTURER.*

BY WILLIAM H. BRYAN,
St. Louis, Mo.

When an engineering structure of magnitude is to be erected, what general plan of procedure should be followed in order to insure that the finished work shall be best adapted for the intended purpose and shall involve the minimum investment of capital consistent with proper construction, and the minimum cost of operation and maintenance?

In the erection of buildings, the precedent of placing the work in the hands of a skilled architect has long since become well established. In civil engineering, the construction of railways, bridges and roofs is universally intrusted to engineers. In the newer branches of mechanical and electrical engineering, however, it has only recently become the practice in this country to engage consulting engineers. The principal reason for this has been that there have been heretofore but few specialists who have devoted their attention exclusively to this class of work. The few well-trained men in these fields early connected themselves with manufacturing or contracting companies, or entered into these branches of work on their own responsibility. The natural disinclination of the purchaser to ask for expert advice from an engineer—however competent and experienced—who is known to be interested in the manufacture or sale of some specialty, and whose opinion is not unnaturally open to the suspicion of bias, left him no course but to proceed on his own responsibility, with results which were often as unsatisfactory to the manufacturer as to himself.

This situation has, however, in a large degree changed, owing to the large number of excellent engineering schools, and the very thorough courses of theoretical and practical training which are there given. These, coupled with the large number of trained and experienced men who have been connected with prominent manufacturing and constructing companies, and with the installation and operation of large plants, have now rendered available the services of many men of thorough technical training, supplemented by years of practical experience in actual construction. Many of these have no connection with the manufacturing, selling and contracting interests, and their judgment is not, therefore, open to the suspicion of bias in favor of or against any special manufacturer.

It is becoming more and more the custom, therefore, to place the same confidence in the consulting, mechanical and electrical engineer which has long been reposed in the architect and civil engineer. He is called in at the earliest stages of the development of the enterprise, for advice as to the general outline and arrangement of the scheme, its probable cost, the expense of operation and maintenance, and the returns which may be expected from the investment. He makes a preliminary reconnoissance and report, giving this data. If these are approved, he then makes a more detailed study of the problem, mapping out the general scheme more definitely, selecting the particular system or type of apparatus best suited to the local conditions of service, and preparing general plans and specifications. These he accompanies with more detailed estimates of cost. When these are approved by his principals, proposals are asked for, and when received, the engineer assists the purchaser in canvassing and comparing them and in selecting that proposal—not necessarily the lowest—which seems best to meet the requirements of the work in hand.

The engineer then assists his clients in drawing up the final contracts, supervises the work during construction and makes such final inspections and tests at completion as are necessary to determine whether the specifications have been complied with.

This has long been the accepted custom in England, where the same difficulty of securing competent and unbiased engineers has not been encountered. No trouble has been met with in that country in applying the same rules to these branches of engineering which are universally followed in other fields.

As might be expected in any new department of engineering, however, the relations between the purchaser, the engineer and contractor have not always been harmonious. The manufacturer frequently feels that he has been imposed upon; the engineer is often hampered by incompetent or unscrupulous contractors, and between the two the purchaser himself is sometimes at a loss for a proper solution of the difficulty. While it is true that most contracts of this character are carried through satisfactorily, it must be admitted that misunderstandings are more frequent than they should be.

The discussion of these differences has recently taken tangible form both in this country and England. In the latter country, the manufacturers and engineers recently met, and succeeded in agreeing upon a number of standard clauses for specifications, which removed many of the objections and criticisms from both points of view. It has been suggested that this work of preparing standard specifications would come properly within the province of the national engineering societies, but if these bodies do not take the matter up, something might be accomplished by the engineers and manufacturers getting together for mutual exchange of views, as was done in England.

The present misunderstandings may be traced to a few serious causes. In the first place, the mechanical and electrical fields of work have, unfortunately, been embarrassed by too great a number of incompetent and inexperienced manufacturers and contractors, poorly equipped for good work, and with but limited intelligence and skill. To these have been added a more than ordinarily large percentage of contractors who are not altogether scrupulous as to their methods, and whose object is to finish the work in almost any sort of shape which will pass muster. These incompetent, inexperienced and unscrupulous contractors—though relatively few in number—have detracted from the good reputation of work of this character, and have forced upon the consulting engineer the necessity of inserting in his specifications the most rigid requirements as to the character of workmanship and material, inspections and tests, which would be unnecessary if it were certain that the work would be awarded to contractors of established reputation, ability and skill.

Furthermore, it has been found that some manufacturers are slow to adapt their designs and patterns to advanced and improved practice. Experience having shown the clear and decided superiority of certain designs, the engineer is justified in embodying them in his specifications, in spite of the fact that some manufacturers will attempt to force the use of antiquated forms.

Again, the manufacturers are often careless in making guarantees. Some of them do not hesitate to meet any desired figures, if a competitor does so. Often they will oblige themselves to do what is impossible with the type of machinery they offer, and trust to luck, or careless inspection or testing, to get the work accepted and paid for.

The grievances of the manufacturers have recently taken shape in papers and discussions in the electrical press and may be briefly summarized as follows:

First—That the engineer appears unwilling to receive suggestions or advice from the manufacturers, as such action might detract from the "dignity" of his position, and that specifications, therefore, often contain many annoying and expensive provisions, sometimes impossible of fulfilment.

Second—That the engineer does not always familiarize himself with the facilities and standards of the manufacturer, and thus sometimes calls for special designs which can only be made, if at all, at greatly increased expense, whereas standard apparatus would frequently answer the purpose equally well.

Third—That if the manufacturer is required to guarantee results, he should not be hampered as to details of design or construction. In other words, the consulting engineer should not tell the manufacturer how he should build his machine, but simply hold him responsible for results.

To these it may be answered, that no harm can be done by full and free consultations between the manufacturer and the engineer. They have a common object in view, namely, the securing of the best results. It is natural that the engineer should reserve unto himself a due degree of dignity, but he should not let this characteristic stand in the way of the best service in the interest of his clients.

The demand for special machinery, however, presents greater difficulties. It should be remembered that electrical developments have been so rapid in recent years—and with them the construction of special steam engines and appliances—that a large percentage of the work has necessarily been special. Furthermore, this condition must continue, for the reason that the methods of generating and distributing electricity on a large scale, over wide areas, for endless varieties of purposes, have by no means reached uniformity of practice or system, and are not likely to very soon. The necessity for special machinery will, therefore, remain with us indefinitely and will continue to cover a large percentage of our work. We must not lose sight of the fact that to attempt to carry the idea of standards too far will surely result in hindering improvements and stifling progress.

I do not desire to be understood, of course, as decrying the use of standard apparatus for that large and increasing percentage of cases for which it is eminently well adapted. The manufacturers deserve great credit for reducing their machines for different classes of service to standards, and the engineering profession is under many obligations to them for doing so in so thorough and excellent a manner. The reduced cost of standard apparatus—the fact that in using it one follows precedent, that repairs can be more quickly and more cheaply obtained, and that when secured, the different parts are actually interchangeable and will fit, and the further fact that standard machines can usually be secured in less time, being frequently carried in stock—all these are points of tangible advantage which no conscientious engineer can afford to overlook. Standard apparatus, however, is only possible when permanency of type and a reasonably constant demand in large quantities is assured. While it will frequently pay the engineer to modify his plans so as to use standard apparatus, there is a point beyond which he cannot go. In such cases he must use special apparatus more closely adapted to his particular needs. All these points must be given the most thorough consideration, and before requiring special work the engineer must satisfy himself, beyond doubt, that his principal's needs can better be supplied in this manner, even at the increased cost, and in spite of the greater risks which always accompany the use of new and untried apparatus.

The contention that when a manufacturer guarantees results he should be allowed to design and build the machine in his own way may be granted, in so far as the guarantee can be made to cover every possible valuable feature. When a reasonable number of manufacturers, however, have adopted certain designs and processes of unquestioned superiority, and where these have an important bearing on the life and reliability of the machine, its freedom from annoying interruptions, and which reduce or avoid the necessity for close and continued attention, is it

* Paper presented at the Niagara Falls meeting (June, 1898,) of the American Society of Mechanical Engineers.

proper to write the specifications so as to limit competition to machines of this advanced type?

Contractors frequently object to specifications which include a deduction for delay in completing the work, but which allow no extra compensation for finishing the work earlier than the date specified. When it is possible for the purchaser to make use of the plant at the earlier date, this criticism is well founded. It is usually the case, however, that the earlier completion in no way benefits the owner, because other equally important contracts may not be finished, or because the dates of leases or contracts for service from the plant cannot be brought forward. The delay of any one contractor, however, might readily cause the purchaser serious loss.

Another objection made by the manufacturer—and one which is not wholly without justification—is the unnecessarily exacting requirements of some specifications, and the annoyance to which they are subjected by the engineers. It is unfortunately true that our profession has been no more fortunate than others in keeping out of its ranks the incompetent and the unscrupulous. These men have brought disgrace upon the profession, and the objection of the manufacturers to being handicapped by them is well founded. There is, however, no reason now why the purchaser—even though absolutely unfamiliar with work in this field—should make a mistake in selecting an engineer, as a very little investigation will enable him to ascertain the character, ability and experience of the man under consideration.

The engineer stands between the purchaser and the contractor, and while he may sometimes insist upon his client's rights to an extent which may appear unjust, he nevertheless recognizes the purchaser's obligations as well, and will see that his end of the contract is equally well maintained. In this way unreasonable requirements may be avoided, prompt payments secured, and the acceptance and settlement made at the proper time and along reasonable lines.

Unfortunately there are some manufacturers who think the consulting engineer unnecessary, and that the business could be better transacted directly between the manufacturer and purchaser. This would be true if the purchaser were always competent to judge of the relative merits of the different systems of apparatus. Unfortunately the agent of the manufacturer cannot always be trusted implicitly as to recommendations, for two reasons: First, he has not the time to give to the detailed study of the problem which the consulting engineer must give in order to make a proper selection; second, his recommendations are too often biased by a desire to sell standard apparatus, or some specialty of his own, which could be used for the work, although less advantageously than something else.

It is here that the engineer serves his client best, in seeing that the proper apparatus is selected, and that it is bought at reasonable figures. The days when the salesman with the glibbest tongue did the most business are fortunately passing away, and the small manufacturer has as good a show to do business with the engineer as one of longer standing, providing his apparatus is clearly the best for the work.

The engineer compares machines on as nearly the same basis as possible. So far as the character of the machine will permit, he requires all proposals to be on the same apparatus. When this is impracticable he specifies capacities, results, and general type or construction, leaving the manufacturers to vary the details in accordance with their own designs and practice. Such proposals, however, should be accompanied by ample data, so that the points of agreement and difference may be clearly brought out. With these data before him the engineer is prepared to analyze the bids, and to make a recommendation based upon merit alone, irrespective of the name-plate which may be attached to the machine.

It is not meant by this that no weight whatever is to be given to long experience and established reputation, as there are many details which cannot be inquired into, and must be left to the manufacturer's judgment. No conscientious engineer, however, will let the mere reputation of a manufacturer carry undue weight.

Early in my own practice I learned that while elaborate and detailed specifications, embodying all sorts of unusual and peculiar requirements, might impress the non-technical reader, and might even gratify the purchaser, they invariably limited competition, and led to excessive prices and annoying delays, and that by purchasing machines as nearly standard as possible, and by modifying the contract to a reasonable extent, to suit the manufacturer in unimportant details, much better terms could be made, without increased trouble to either the purchaser or the engineer.

The contract forms submitted by many manufacturing companies are unfair to the purchaser, in that they are wholly one-sided, and are intended to protect the seller in every way possible, while the rights of the purchaser are given but little consideration. Such contract forms are far too common, and for the credit of the profession it is hoped that these may be modified and brought to a more equitable basis.

The ordinary proposals submitted by many companies are equally unfair. Perhaps the most flagrant instance of this is the statement in many bids that they are not effective until approved by an executive officer. Such proposals are not worth the paper they are written on, and should not be considered for a moment by any self-respecting engineer, as they in no way bind the bidders, and their acceptance simply ties up the purchaser. Instances are not lacking where manufacturers have taken advantage of this clause to repudiate bids apparently made in good faith. So common is this practice that it has become necessary to incorporate a clause in the "Notice to Bidders," to the effect that proposals which are not made in good faith will not be considered.

Another unfortunate practice is that which many manufacturers have of asking the return of their proposals and accompanying data as soon as the award is made. These papers are necessary to the purchaser and the engineer, to make a complete record of the transaction, and should be retained by them.

On the other hand, it must be admitted that some engineers' specifications are unfair to the manufacturer. The points on which these complaints are based have been given due consideration, and in my own practice have led to the following rules:

First—When it is desired to permit the bidder some elasticity, and not to require him to adhere rigidly to the specifications, the "Notice to Bidders" contains a clause reserving the right to waive informalities.

Second—The engineer is made the arbitrator of all disputes, but appeal is always permitted to a referee or referees. If the contractor thinks he is being treated unfairly he may avail himself of this privilege.

Third—A clause is frequently inserted to the effect that where a special make or type of apparatus is mentioned in the specifications, it is not intended to mean the exclusion of all others, but simply as establishing a standard of excellence. The bidder may substitute other apparatus in his proposal, the engineer reserving the right to judge as to whether the article offered is equivalent to that specified.

Fourth—Where the work is such that it is impossible to go into details very fully, and where the apparatus is of such a character that different builders offer different types of construction, which accomplish substantially the same results; or where it is desired to secure the benefit of the most recent improvements, a general clause like the following is sometimes inserted:

"While it is believed that the following specifications properly cover the needs of the purchaser at this time, they are not necessarily final. Bidders are invited to submit alternative propositions embodying any other types of apparatus, or other details of construction, which in their judgment may seem as well, or better, adapted to the purchaser's needs."

It is to be hoped that this presentation of the matter may result in a better understanding among all parties interested, as to mutual obligations and responsibilities. I believe I may say for the engineers that they will meet the manufacturers fully half way in an effort to reach a more satisfactory basis of co-operation, and to bring about a higher standard of design, workmanship and efficiency, and a more uniform and equitable definition of contract relations.

ALTERNATING CURRENT TRANSFORMERS—FROM THE STATION MANAGER'S VIEWPOINT.*

BY W. F. WHITE.

In the early days of alternating central station development many a sale of alternating central station equipment was lost to direct current competitors by the facts, figures and fancies which the salesman of direct current apparatus was able to advance concerning the wastefulness of energy, the expense of maintenance, and the danger to life which purchasers must accept as inseparably wedded to any transformer system.

Notwithstanding that the danger to life was unfortunately made much of, and the facts grossly misrepresented, still the correctness of many of those arguments, in the light of present knowledge, stand up remarkably well under the scrutiny of qualitative analysis. And it is even more remarkable, in view of the natural tendency to exaggerate induced by zeal to make sales, how little, if any, were the facts of these evils overdrawn or magnified. Quantitative analysis in fact proves that most figures then given to show the amount of transformer "leakages" were understated. On the part of salesmen this was undoubtedly more a mistake of the head than of the heart, for while some few of them knew the results of some isolated tests of some particular size of one type or manufacture of transformer, no one, whether salesman, engineer and designer, or manufacturer, had any knowledge or conception of the cumulative effect of transformer losses on the station output. Such little knowledge as had then been acquired related more to the transformer efficiency under certain percentages of rated load than to all-day efficiency, or the 24-hour ratio of energy output to energy absorbed under average conditions.

Little if anything was known of transformer core losses, and the effect of power factor on station and line capacities had not had consideration. As long ago as 1892 the writer, in making a careful examination into the operations of one of the then largest alternating stations in this country, made the discovery that with a net meter rate to consumers of about 20 cents per 1,000 watt hours, the income per KW. hour output at the switchboard was only about six cents, showing an average loss from station switchboard to consumer's meter of about 70 per cent.

Current was supplied, in accordance with the then universal practice, through one or more transformers for each customer. In two or three cases for

*Paper read at the Fifteenth General Meeting of the American Institute of Electrical Engineers, Omaha, June 29, 1898.

large installations as many as 18 or 20 transformers were erected for a single customer, no transformer of more than 75 lights capacity being used, the transformer primaries connected in multiple, but the secondaries feeding entirely distinct and separate circuits.

Of each 1,000 watt-hours output at the switchboard it was estimated that approximately 300 watt-hours were delivered through the customer's secondary meter, 600 watt-hours were accounted for by transformer core losses, leaving 100 watt-hours to be accounted for by transmission and other losses.

A statement of these conclusions to a well-known manufacturer, who supplied the wattmeters and many of the transformers, elicited the opinion that either the primary meters registered too fast or the secondary meters too slow.

A meter expert from the factory accordingly spent several weeks in testing all primary and secondary meters, found them correct, and proved that the apparent discrepancy was not due to the meter end of the plant equipment. With the writer's recommendation that a three-wire secondary network be erected, using 100-volt lamps, and fed through large transformers at frequent centers of distribution, the matter was dropped; but there is no doubt that the proportion of the output attributed to transformer losses was approximately correct.

Since that time it has been the writer's good fortune to be in touch with a considerable number of alternating plants, giving him knowledge of their operating results, and he does not hesitate to assert that very few plants exist, giving continuous service, using separate transformers for individual customers and charging from 12 to 20 cents per 1,000 watt-hours, secondary meter measurement, whose income per KW. hour output at the switchboard exceeds from four cents to seven cents. In other words, the transmission, transforming and distribution losses are commonly as much as 200 per cent. of the customers' demand, as shown by the customers' meters. This does not mean operating expenses three times as great as if all these losses were eliminated, but it does mean that large expenditures are made for fuel and feed water for the keeping warm of numerous transformers operating about twenty hours per day with open secondaries. And great numbers of small transformers also mean great variations of secondary voltage, large bills for lamp renewals, unsatisfactory service, and a reduced number of lamps which can be served at any instant from a given generator capacity. To show the benefits to be derived by using a secondary network, fed by large transformers working in multiple, but located one at each feeding point or local center of distribution, as compared with the use of small transformers, one or more to a customer, the writer presents some results accomplished by an existing plant in remodeling its transformer system in accordance with these ideas.

January 1, 1895, this plant was serving 16,702 incandescent lamps (16 CP. equivalent) through 547 transformers of 22,190 lamps rated capacity, each transformer averaging 40.6 lamps capacity and serving 30.6 lamps. The transformer load, with open secondaries, was, as near as could be determined, about 80 amperes at 1,000 volts. In view of the fact that the maximum load never exceeded 50 per cent. of the lamp capacity connected, it was evident that a very considerable reduction could be made both in the number of transformers connected and in their aggregate capacity by the use of a secondary network. The theoretical limit was to reduce the transformer capacity to equal the maximum load, which would lower the capacity connected from 22,190 lamps to about 7,000 lamps, a reduction of about 64 per cent. This limit was evidently impossible of attainment because of the large number of isolated installations, especially in the residence districts, requiring individual transformers, which of necessity must generally be of capacity equal to several times the average load. A system of three-wire secondary networks was laid out, and estimates made showing a possible reduction of almost 80 per cent. in the number and of about 50 per cent. in the lamp capacity of transformers connected. A large number of tests of core losses of all sizes of transformers in service was then made for estimating the total core losses for the plant and for comparisons with the estimated core losses of the large transformers to be erected in replacing the old.

An illustration of one or two of these comparisons may be of interest. One installation of approximately 700 lamps was fed through a large bank of small transformers having an aggregate core loss of 4,440 watts, which could be replaced by two transformers having a combined estimated core loss of 310 watts. On the basis of the number of watt-hours per pound of coal then being produced by the plant, not taking into account any line losses, this example shows the following results :

4,400 watts, 38,894,400 watt-hours per year, requires 190.6 tons of coal.

310 watts, 2,715,600 watt-hours per year, requires 8.4 tons of coal.

Annual saving, 36,178,800 watt-hours, 182.2 tons of coal.

The annual income from this installation was about $2,100 at 12 cents per 1,000 watt-hours. With a secondary output of about 17,800,000 watt-hours, and transformer core loss of about 38,894,400 watt-hours, the income per KW. hour output at the switchboard for this installation was evidently less than four cents, and the core losses were more than double the total secondary output.

In another case, one section of the city, comprising ten city blocks, was fed by one dynamo and circuit through 71 transformers, having an aggregate rated capacity of 4,482 lights and aggregate core losses of 10,402 watts (estimated), or 91,121,520 watt-hours per year.

To replace these transformers a three-wire secondary network was erected, supplying all customers, and fed by five 400-light transformers, located at as many feeding points or local centers of distribution. Each transformer was provided with primary and secondary switches, by means of which each night all transformers were thrown into service from dusk until midnight, at which latter hour four transformers were cut absolutely out of circuit. On a yearly average five transformers were in circuit about six hours per day and one transformer the remaining 18 hours per day. The combined core losses of the five were about 1,250 watts, and for the hours in service aggregated about 4,380,000 watt-hours per year. Some results of the above changes on this one circuit therefore were as follows :

Number of transformers.	Lights capacity.	Total core losses. Watts.	Total annual core losses. Watt hours	Equivalent tons coal.
71	4,482	10,402	91,121,520	446.7
5	2,000	1,250	4,380,000	21.5
Saving......	2,482	9,152	86,741,520	425 2

A reduction of over 95 per cent. in core losses and a saving for one year in cost of fuel alone of $815.40 were effected for this one circuit. These examples were extremes, because the lighting covered by them was concentrated, and because in most residence and outlying business districts few changes in the number and capacity of transformers could be made. The results shown by the last example were therefore much above the average for the whole plant, but serve to show the possibilities of such changes and the methods pursued in this case.

Some results for the plant as a whole may therefore be fairly indicative of what other average plants operating under similar conditions may accomplish in the same direction, and were as follows :

Time.	Lamps connected.	Transformers connected.	Total capacity.	Average lights capacity.	Average lights served.
Jan. 1, 1895.	16,702	547	22,190	40.6	30.6
" 1, 1896.	19,282	201	13,865	69.	90.1
" 1, 1897.	20,262	152	13 498	88.8	133 3
" 1, 1898.	23,643	141	14,916	106.	167.7

Year.	Income.	Switchboard output KW. hours.	Income per KW. hour output.	Increase of income per KW. hour output.
1894	$59,012.71	928,400	$.0635	....
1895	54.231.67	791,752	.0681	7.7 per cent.
1896	51,115.29	551,064	.0933	16.9 per cent.
1897	56,317.42	508,070	.1108	71.5 per cent.

Year.	Actual KW. hrs. output.	Estimated KW. hours output — basis 1894 conditions.	Estimated KW. hours saved by change.	Estimated saving in coal—1894 basis.	
				Tons.	Cost.
1894	928,400	......	......	......	......
1895	791,752	851 042	63,290	310.2	$670.91
1896	551,064	809,689	258,625	1,267.8	2,641.42
1897	508,070	886,888	378,818	1,856.9	4,015.13

It must be borne in mind that the number of 16 CP. equivalents connected January 1, 1895, was 16,702, and increased by January 1, 1898, to 23,643, or more than 41.5 per cent. The savings estimated in last table are based on the conditions at the beginning of this period, i. e., the same number of transformers and the same transformer capacity. But if the same conditions had obtained throughout, an increase of 41.5 per cent., or 226 transformers, of 9,208 lights capacity, would have been added to supply the new lights connected. And while only a part of the core losses of the transformers in service January 1, 1895, was saved by the change, the entire losses of the 227 transformers, which would have been required by increased business, were saved. It is therefore perfectly safe to add 50 per cent. to the savings shown in the last table, in estimating actual benefits. From reduced core losses alone, therefore, there is an annual saving of approximately $6,000.

In core losses alone, the savings already effected have more than paid all costs of the entire change of lamps, meters and transformers (for because of a simultaneous change from 52 volts to 106 volts, secondary, all lamps and meters also had to be changed), and of the erection of secondary network; and the annual saving of $6,000 is equal to 6 per cent. interest on $100,000, secured without one dollar invested.

To be certain that the saving of fuel was in proportion to the reduction in KW. hours output, as estimated, the plant efficiency under the changed conditions must be known. It is therefore pleasing to note that, using coal from the same mine most of the time, the watt hours output per pound of coal actually increased for 1896 by 3.8 per cent., and for 1897 by 5.9 per cent. over 1895, so that the saving in fuel was at least not less than in proportion to the saving in KW. hours output.

Some incidental advantages of the change may be mentioned :

First—Under the old plan, the 6,941 lights added would have required about 9,200 lights additional transformer capacity, of 40 lights average size, of $1 per light average cost, giving an investment saving of $9,200.

Second—The transformer load, with opened secondaries of 80 amperes, was reduced by the fall of 1897 to about 30 amperes, notwithstanding an increase of about 25 per cent. in the number of lights connected. A saving of 50 amperes at 1,000 volts represents a capacity to serve, without additional

station or line equipment, approximately 1,000 16 CP. equivalents, all burning at one time, or fully 2,000 16 CP. equivalents connected.

Third—Formerly as many as a dozen transformers were frequently burned out in a single thunderstorm. Ten per cent. of the transformers connected would be a conservative estimate of the number burned out each year from various causes. Of the new transformers connected during the past three years only one has failed from any cause, and that one was defective and burned out under light load almost immediately upon being put in service. Transformer repair costs are therefore practically eliminated.

Fourth—Incandescent lamp renewals have been greatly reduced. Using lamps from the same factory of the same efficiency and bought at the same price per lamp, the cost (estimated) of renewals per KW. hour consumed by the lamps has been reduced from \$.0081 in 1895 to \$.0057 in 1897, a reduction of 29.6 per cent. This saving represents the advantage of regulating the secondary voltage by pressure wires connected to the secondary network, as compared with the former method of regulating the primary voltage by station transformers.

Fifth—The principal remaining incidental advantage is the uniformity of voltage, bringing uniformity in quality of service and the consequent satisfaction of customers, the value of which cannot be estimated in dollars or percentages. These are some actual results, and such as any plant operating under similar conditions can achieve at small expense, if the changes are well planned, and the replaced apparatus sold to the best advantage.

In this connection, attention must be called to one other fact, which is that central stations using separate transformers for individual customers have the great majority of their transformers working on open secondaries probably 80 per cent. of the time. The best transformers have a power factor of about 50 with open secondaries, and of fully 99.9 with almost any load they carry in practice. It is therefore perfectly credible, and the writer has demonstrated it to be so by many actual tests on various plants, that the average power factor of plants operating under above specified conditions is approximately 65.

It scarcely needs demonstration that if, instead, a secondary network is used, and only such transformers allowed to remain in circuit at periods of light load as are required to advantageously carry such load, the average power factor will be approximately 100. The volt-ampere hours therefore, calculated from the station voltmeter and ammeter readings, give approximately the watt-hours output. But almost all existing plants use separate transformers for individual customers, and the great majority of them do not have primary wattmeters on their switchboards, and do calculate their volt-ampere-hours output as equivalent to watt hours, getting results about 50 per cent. in excess of the facts. They therefore are able, apparently, to show 50 per cent. more watt-hours per pound of coal and 33⅓ per cent. less expense per KW. hour output than another station operating under the same conditions and fully equalling theirs in actual performance but which accepts the primary meter readings as the basis of estimate.

As a matter of fact, the usual disparity is greater than the percentages given, because most station managers in erecting primary switchboard meters follow their æsthetic inclinations, and use ornamental glass covers which are particularly susceptible to the admission of dust and grit, with the result that the meters rapidly slow down. It is highly probable therefore that in some stations the volt-ampere-hour record would show twice the number of apparent watt-hours per pound of coal, and one-half the expense per apparent KW. hour output that would be shown by the record of the primary meter already erected on the switchboard, which tends only to show the worthlessness of data from different plants for purposes of comparison, unless the local conditions are known in each case.

This digression is permissible, we hope, because the average power factor, so far as we know, has never been taken into account, and because for that reason much misleading alternating central station data is in circulation.

Purchasers and users of transformers should insist that transformers meet certain requirements, or be rejected, and some of these requirements will be stated.

Where transformers are used for feeding networks, the secondaries in multiple, small core losses are of much greater importance than close regulation, and should be kept at the lowest practicable point. The regulation will be cared for by treating the transformer and feeder drop together, through the use of secondary pressure wires.

Where the transformers are entirely independent, feeding separate secondaries, close regulation must be had and the core losses made as low as the adopted regulation will permit. With constant full load the temperature must not rise to a high point, and should not exceed 50° centigrade above the surrounding air. This is important not only because of the increased life of transformer insulation through low temperatures, but also, and possibly to a greater degree, because magnetic fatigue is a certain follower of high core temperatures. If therefore the core losses might be increased 50 per cent. or possibly 100 per cent. through high temperatures, the cost of these core losses, as shown in case of the plant above, makes argument unnecessary as to the desirability of having transformers run cool.

The transformer case should be filled with oil, because of its insulating qualities, its exclusion of air and because of its assistance in maintaining the low temperature desired.

The insulation resistance between the primary and secondary windings should be able to stand up under not less than 10,000 volts, alternating, difference of potential for transformers having 1,000-volt or 2,000-volt primaries, and the writer would strongly urge a 15,000-volt alternating test. If both the primary and secondary windings are on the core, the same insulation resistance should be required between either winding and the core as between the two windings. The use of grounded shields placed between the primary and the secondary windings, the grounding of the shell or core, the grounding of the secondaries, the placing in each customer's service connections of any device to automatically open the circuit of such customer in case of an unusual difference of potential, are all practices that are opposed as expensive, as liable to cause, more than to prevent trouble, as complicating existing practice, and as wholly unnecessary.

Proper insulation is sufficient protection against the damages sought to be avoided. Station managers as earnestly desire complete safety for life and property as the Underwriters' Association, but vigorously oppose the introduction of any unnecessary devices that are expensive to install and to maintain. That Association, in seeking protection for the secondaries, should do so through sufficient transformer insulation and low temperatures. Both of these requirements mean increased cost of production and higher selling prices, but as the consequent increased economy makes the increased cost a profitable investment, no reasonable manager will object. In this way the ends sought will be best attained, and the interests of all parties duly safeguarded.

The General Electric Company owed on July 1, 1898, \$1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

WHAT MARCONI HAS SO FAR ACCOMPLISHED.

The Dublin *Mail* publishes the following account of an interview of one of its representatives with Signor Marconi. The latter said:

"We have an installation that sends messages a distance of 14½ miles across salt water between Bournemouth and Alum Bay, Isle of Wight. This was done to prove that weather temperature and climate had no power to affect the working of my system. It proved incidentally that the invention can be worked by any capable telegraphist without any special training whatever. It was also proved that any vessel coming within 12 miles of either of the two stations, which had on board an instrument similar to the ones used at the stations, could communicate with the latter. A small tug of ours communicated with the shore at a distance of 18 miles, although the weather was extremely unfavorable. I found that it is easier to communicate between ship and ship or between ship and shore than it is to exchange messages between stations on land. When last year the Italian Government kindly placed at my disposal two ironclads for purposes of experiment, I established communication at a distance of 12 miles with the shore and between the ships themselves. The invention is now being used in the Italian Navy. The size of the vessel upon which the invention is used does not affect its working, the best results having been obtained on the small tugboat referred to off the Isle of Wight. The sea was then very rough, and we had at times 2 ft. of water in the cabin, all the instruments being drenched with it, but without impairing their usefulness. On that occasion communication was established with the island 18 miles away. Captain Kennedy, R.E., who was on board, stated these results in a public lecture delivered at Whitehall, and expressed his complete satisfaction at the success of the experiments. In war the invention is of the greatest use to torpedo boats or destroyers, which, with the apparatus on board, would be able to communicate at a considerable distance with the battleships of the squadron to which they were attached. This has been proved by experiments made in the navy by one of the great Powers. In the mercantile marine the invention is of even more practical utility than on board a man-of-war. Provided lightships and lighthouses are fitted with my apparatus, ships in foggy weather can be warned of danger from the lighthouse or lightship when the flashlight or the sound of a bell could not reach the vessel. Ships could also communicate with each other and interchange a warning. The warning apparatus in a lighthouse can be so set as to sound the alarm to any ship coming within a radius of 10 miles, and the latter will know from the kind of signal received what particular lighthouse it is that has signalled. This is done by means of a reflector moved around the receiving instrument on the principle of a dark lantern, through which only the electric rays penetrate. I have been informed by an evening newspaper of the 20th inst. that when a party from the House of Commons visited the dockyard at Portsmouth they found officers and men of the Royal Navy being instructed in the working of wireless telegraphy, which I have frequently discussed with British officers of both the army and navy."

New Use of Liquefied Air.

Prof. Charles E. Tripler, the discoverer of a process of making liquefied air, in a recent issue of the Philadelphia *Times* says regarding the possibilities of it when used in warfare:

"Among them are the immediate application to the firing of projectiles, the explosion of shells and torpedoes, the driving of vessels at greater speed with less consumption of coal, the cooling of the turrets in action from the torrid heat to a moderate temperature, thus enabling the men to handle the guns with better efficiency and adding to their en-

durance, the cooling of the stoke-holes and all parts of a warship.

"The benefits of the foregoing are self-evident. It is now simply a question of mechanical application. The power exists and is ready to be used; it only remains to be determined how it can best be applied. It is a power evidently exceeding any hitherto employed. Its limits cannot yet be defined, from a gentle, cooling breeze to the power necessary to drive the largest vessel or hurl the heaviest projectile. This is no guesswork nor mere speculation. These are fundamental facts that I have established:

"First—Liquid air can be manufactured easily, cheaply and in large quantities.

"Second—A cylinder can be charged with liquid air under conditions which give an expansive force equal to or greater than that of gunpowder, or an explosive exceeding gun cotton or dynamite.

"Third—It cannot be exploded except by a spark (produced in any desired manner) and being unaffected by concussion, it is perfectly safe to be handled and can generate any pressure desired at will.

"Fourth—Liquid air can be produced anywhere and at any time. Any ship could carry and operate the mechanism for its production.

"Fifth—Liquid air is from 20 to 100 times as powerful as steam, and it can be applied as easily as steam to drive the engines of a ship.

"These, I repeat, are not guesses, but established facts, and inevitable corollaries from such facts."

SOME NOTES ON THE ELECTRO-DEPOSITION OF PLATINUM.*

BY SHERARD COWPER-COLES.

The resistance of platinum to the action of corrosive acids renders it invaluable for the coating of chemical and electrical apparatus. Considerable difficulties have been experienced in obtaining a satisfactory deposit of platinum, the thickness of the coating being very limited. Smee was one of the first to study the conditions under which good metallic deposits of platinum could be obtained. He obtained the best results with a solution composed of nitro-muriate of platinum, to which sufficient soda was added to render it neutral. He used as an anode a fine platinum wire, oxygen gas being given off from the platinum wire, and no gas evolved at the cathode. Smee designated obtaining bright deposits of platinum as platinating, in contradiction of platinizing. To platinize metals, according to Smee, a strong current is used to decompose the water and drive off hydrogen at the cathode, so as to produce platinum sponge or black. Roseleur has also given considerable attention to the electro-deposition of platinum; he claims to have obtained thick deposits of platinum from a solution composed of 10 parts of platinum converted into chloride dissolved in 100 parts of distilled water.

If any cloudiness appeared in the solution when the chloride was dissolved in the water (due to overheating in the last stage of evaporation), the solution was passed through a filter. One hundred parts of phosphate of ammonia (crystallized) were then dissolved in 500 parts of distilled water, and the solution added to the platinum liquid with brisk stirring, when a copious precipitate formed. To this was next added a solution of phosphate of soda, consisting of phosphate of soda 500 parts, distilled water 1,000 parts. The above mixture was boiled until the smell of ammonia ceased to be apparent, and the solution, at first alkaline, reddened blue litmus paper. When the yellow solution became colorless, it was ready for use; the solution is used hot, with an EMF. of 7 to 8 volts; Roseleur recommends it for depositing platinum on brass, copper and german-silver. As the platinum anode is not dissolved, fresh additions of chloride must be constantly added. The writer has been unable to obtain thick deposits from this solution; the platinum, after it has obtained a certain thickness has a great tendency to exfoliate. For a short time a process was carried on by the Platinum Plating Company, Limited, which was practically identical to the above, with the exception that a small addition was made of chloride of sodium; this solution gives no better results than Roseleur's. Boettger's solution for depositing platinum consists of the double chloride of platinum and ammonia dissolved in water to which a few drops of liquid ammonia are added. The solution is worked warm.

Another solution of Boettger's consists of the double chloride of ammonia dissolved in 8 parts of salammoniac, and another of the double chloride of platinum and ammonia freshly precipitated at a boiling temperature, dissolved in a concentrated solution of neutral citrate of sodium. The resulting liquid is a deep orange color with a feeble acid reaction, and should be worked cold with a current density of about 3 amperes per square foot, and an EMF. at the terminals of the bath of 7.5 volts. If the solution contains about 1½ ozs. of platinum to the gallon of solution, excellent bright deposits are obtained.

Gore, in his book on "Electro-Metallurgy," refers to a solution of chloride of platinum dissolved in one of cyanide of potassium, the proportions of metal being kept at about 1 oz. to the gallon; the bath being used warm. Jewreinoff affirms that the platinum anode is dissolved freely in a solution composed by dissolving 10 parts of metallic platinum which has been converted into chloride in 10 parts of caustic potash in water, the yellow precipitate being dissolved by the addition of 20 parts of oxalic acid in aqueous solution with the aid of heat. To this solution is added 30 parts of caustic potash solution. The solution is strongly alkaline. Jewreinoff has also used another bath for the deposition of platinum in which he converts three parts of platinum into chloride and dissolves this in 300 parts of distilled water, to which is added 25 per cent. of sulphuric acid. He also recommends the use of platinum anodes in this bath.

* From the *Electrical Review*, London.

A New Electric Ship Signal.

An interesting application of the principle of the rotating magnetic field to signaling apparatus, says the *Electrician*, London, is described in some of our Continental contemporaries. This signal system, due to Dr. L. Weber, is intended to replace the step-by-step devices now used for many purposes, but especially for the purpose of signaling between bridge or pilot-house to engine-room on ships. Similar dials are used at the ends of the line in these devices, the signal being given by moving an index lever over the dial at the sending station and causing a corresponding movement of an index hand over the revolving dial. In Dr. Weber's device the sending instrument consists of an endless resistance helix arranged in a circular form on the dial and wound on a resistance frame in the manner of a Gramme winding. This resistance is tapped at three equidistant points by three conductors which are led to the receiving dial. Here they are connected in the three-phase star fashion with three radially disposed magnets controlling a small two-pole armature of soft iron attached to an indicating hand. The current energizing this receiving instrument is furnished and suitably distributed by the sending instrument already referred to by an index lever pivoted in the center of the resistance helix and furnished at its ends with contact pieces touching on the opposite ends of the diameter of the resistance—these contact pieces being terminals of an electrical source, the current from which is differently distributed in the three circuits, and therefore in the magnets of the receiver with every different position of the transmitter lever.

Rapid Transit in London.

While New York is struggling with rapid transit problems, in which it is hard to say whether the engineering, the financial or the political elements constitute the greatest obstacles to progress, London seems to be going ahead and providing its millions with facilities for rapid communication on novel and effective principles. Having outgrown the old smoky and gloomy underground road, the British metropolis is now being rapidly provided with a system of lines mainly based upon the work of the late Mr. Greathead, the engineer and designer of the City & South London Railway, the first of the deep-level, underground electric roads. A description of that enterprise, which connects the north and south portions of London, is unnecessary. Its success, however, has led to the planning of a number of other roads of the same general character, including the Central London Railway, now approaching completion, which, starting from the Mansion House, will run a number of miles through the residential districts at the west. The Waterloo & City Railway is another of them, and has just been completed. It leads from the Mansion House—that is to say, the immediate neighborhood of the Bank of England and the London Stock Exchange—to the Waterloo station of the London & Southwestern Railway, on the south side of the Thames. In this, as in the other tubular electric roads built or in process of building in London, American inventiveness in the field of propulsion by electric power has been freely used, and it is to be noted that in the case of the Waterloo road the very cars employed are of American manufacture, having been built at one of our leading works and representing in their plan American rather than English ideas.

The Waterloo road is a short line. The distance between its termini is only 1½ miles, but it traverses some of the busiest and most substantially built portions of London. The line consists of two tubes, one for the up and the other for the down line, which at the furthest point from the surface will be some sixty feet underground. It is unique in several features. One of them is that there is no intermediate station between its two termini, and the other is that it at no point rises to the surface, as is the case with its prototype, the City & South London, or original "Greathead system" line. While primarily designed for the benefit of the suburban and general traffic of the London & Southwestern Railway, the new line will give rapid communication between two crowded portions of London. The fare locally is to be 2 pence, or 4 cents, and the trip will be made in five minutes, the trains running on five-minute headway, or more frequently if traffic makes this necessary. Altogether this interesting enterprise, of which the formal opening is soon to take place, furnishes a number of important suggestions for American cities and for New York in particular. —*Bradstreet's, July 16.*

The Electric Telescope.

The latest apparatus for telegraphing images to a distance, says the *Electrical Engineer*, London, is the idea of M. Dussand, the inventor of the microphonograph. The image is received in a camera, passed through a rotating shutter pierced with small openings arranged in a spiral, and falls upon a selenium plate, through which is passed an electric current traversing the primary circuit of an induction coil. The apertures of the shutter bring the light of successive parts of the image to the selenium, setting up currents in the secondary circuit of the coil that vary in strength with the intensity of light, according to a well-known law.

The varying currents pass to the receiving instrument, where a very sensitive telephone diaphragm is placed more or less in front of a fixed plate, more or less weakening a beam of light that passes a shutter exactly like that of the transmitter, and moved

in unison with it, and is thrown upon a screen by a system of lenses. The light reaching the screen has the same intensity as the corresponding part of the image. The result is, so the theorists say, that when both shutters are rotated over the entire image in a tenth of a second, the time visual impressions persist, and the entire image is seen on the screen.

LEGAL NOTES.

In the suit brought at Cincinnati by the Westinghouse Electric & Manufacturing Company against the Triumph Electric Company for infringement of a patented device, United States District Judge Clark decided in favor of the Triumph Company, dismissing the suit and putting the costs on the plaintiff.

The Supreme Court of Missouri has given a decision affirming the legality of the franchise under which the Sutter Conduit Company built its conduits in St. Louis some years ago. The decision allows the Sutter Company to string its wires in the conduits and to connect these wires with the houses along its route. It compels the Board of Public Improvements to issue permits to the company.

A preliminary injunction has been asked by the Thomson-Houston Electric Company in the United States Circuit Court restraining the Walker Company, a New Jersey corporation, and the Union Railway Company of New York from making or using certain electrical devices, said to have been invented by Elihu Thomson, and which are alleged to be infringements of patents held by the Thomson-Houston Company. These patents are on electrical commutators or switches, devices and arresters for electric power, lighting circuits, etc. The complainant charges that the Walker Company manufactures and the Union Railway Company uses these devices in spite of repeated protests, and asks for damages in a suit filed.

The right of an abutting owner to compensation for damage caused by the poles and wires of an electric railway in the street is sustained, Jaynes vs. Omaha Street Railroad Company, Neb., 39 L. R. A. 751, and it is said that it is not necessary for this purpose that the road should be an additional burden upon the easement, as matter of law, under a constitutional provision for compensation in case of property damaged for public use.

The killing of a deaf and dumb boy by an electric car fitted with defective brakes, preventing the motorman from stopping it with proper readiness, is held, in Thompson vs. Salt Lake Rapid Transit Company, Utah, 40 L. R. A. 172, to make the street car company liable for damages even if the boy were negligent.

In the suit of the city of Hoboken, N. J., against the Rutherford Railway Company, Judge Lippincott, on the 13th inst. directed the jury to find a verdict for the city and against the company for $23,000, the amount claimed with interest. Judge Abel I. Smith, on behalf of the company, took a number of exceptions and gave notice of appeal to the Supreme Court. The suit was brought to compel the payment of $20,000 which the company agreed to give for a franchise to run its cars in certain streets in Hoboken, but had failed to pay.

The Supreme Court has reversed the decision of the local court which fined Alex. Dow, manager of the Edison Illuminating Company at Detroit, $5 for refusing a factory inspector access to the machinery department of the establishment, and ordered a new trial. The testimony showed that while the inspector was refused permission to enter the engine room by a certain door, he was told that he might enter by another door. The court says it was the duty of the factory inspector to observe reasonable regulations.

Fire and Police Telegraph Convention.

Extensive preparations for the Annual Convention of the Association of Chiefs and Superintendents of Fire and Police Telegraph and Municipal Telegraph Systems, which is to take place in Elmira, N. Y., on August 9 and 10, have been made by Will Y. Ellett, the president of the organization. Mr. Ellett is in charge of the municipal telegraph and telephone system of Elmira. Mr. Ellett says that the people of Elmira will hospitably entertain the visitors. The wish has been expressed that the superintendents and chiefs bring their wives, and while the Convention is in session the women will be cared for.

The Ohio Electric Light Association.

The annual convention of the Ohio Electric Light Association will be held in Sandusky Thursday and Friday, August 18 and 19. About 200, including delegates and their families, are expected. On Saturday, the 20th, the Warren Electric Company and the Sandusky Gas & Electric Light Company will unite in entertaining the visitors. A boat ride to the islands will probably be arranged for. The West House will be made the headquarters of the convention.

"Steam."

The Babcock & Wilcox Company, New York, have just issued the thirtieth edition of their book "Steam." This book has been for years one of the standard works on water-tube steam boilers and on boiler practice generally. The present edition contains much new matter. It is beautifully printed and illustrated and substantially bound, and is sent free to anyone in any way interested in the generation of steam.

THE NEWS.

What is Going On in the Electrical World.

STREET RAILWAYS.

Berrien Spring, Mich.—The council has granted a franchise giving the proposed electric road from South Bend to Benton Harbor right of way through the corporation.

Bennington, Vt.—The work of laying the rails over the five mile connection between North Bennington, Vt., and Walloomsac, N. Y., on the Bennington and Hoosick Valley Electric Railroad was completed a few days ago. This village and Hoosick Falls are now united by a well equipped road about 16 miles in length, and Bennington is given another outlet to the Fitchburg Railroad.

Biddeford, Me.—Col. Charles H. Prescott has purchased a controlling interest in the Biddeford & Saco Street Railway and will improve the line.

Birmingham, Ala.—The Birmingham Traction Co. has begun operating its Gate City line with electricity; it was formerly a steam dummy line, and was considered something of a nuisance, but has been transformed into one of the best electric lines in the South.

Buffalo, N. Y.—The "Times" says: "The proposed Buffalo, Hamburg & Aurora Electric Railway will be built. U. L. Upson, secretary and general manager of the company, has returned from New York City, where he went in company with President Walter Phelps and Vice-President Adam Benzing to talk over the matter with the stockholders of the road. The contract for the construction of the entire line will probably be signed in a few days."

Cleveland, O.—A fire at the Wilson avenue car houses of the Cleveland Electric Railway Company on the 11th destroyed the building and damaged a number of cars. The total loss was not more than $11,000.

Denver, Col.—The Colfax Electric Railway Company has been granted a franchise by which it secures right of way to Montclair.

Doylestown, Pa.—The Newtown Electric Railway Company has filed notification of its purpose to extend its line to Doylestown. The directors of the company are Thomas P. Chambers, Edward H. Buckman, George C. Worstall, Thaddeus S. Kenderdine, William T. Wright, George C. Blackfan, Ashbel W. Watson and Alexander Chambers.

Elizabeth, N. J.—The Union County board of freeholders have ascertained the cost of widening Westfield avenue from this city to Plainfield, which according to the engineers' estimates will amount to nearly $300,000. Bids for the trolley franchise or right of way over the new road will be advertised for and the freeholders hope to get at least half of the cost of the improvement from the sale of the franchise. Ex-Congressman John Kean has already made an offer of $100,000 for the right to run cars over the road, the length of which is twelve miles.

Franklin, Mass.—The Milford, Franklin, Woonsocket & Attleboro Street Railway Company was organized here recently with Hon. Joseph G. Ray as president and Edgar K. Ray as treasurer. There is probability that construction may begin the coming fall. The intention is to build from the State line to Unionville, Franklin and the Attleboros; and also to run from Central street in Milford to North Bellingham, on the south and west side of Bear hill to Unionville from North Bellingham, where connections will be made with main line.

Hudson, N. Y.—The Hudson Street Railway Company intends to extend its line to Claverack and Philmont and at the latter place connect the county seat with the Harlem Railroad. It is understood that a New York syndicate has purchased the road as part of an electrical scheme of large proportions. The projectors of the enterprise intend to harness the waterfalls of Jansen Kill and by means of immense generators produce electricity for the operation of the railway, for manufacturing and other purposes. It is expected that from 2,500 to 3,000 horse power can be developed. The company is already incorporated under the laws of the State of New York as the Jansen Kill Power Company.

Lockport, N. Y.—The Lockport & Buffalo Electric Railway Company has been granted permission to lay a set of connecting tracks on West Avenue and Transit street between those formerly known as the Erie line and local street electric road and operate thereon. The company will have to take up the bond of the former Lock City electric road. The franchise granted is for forty-seven years, it being the remainder of the one granted the Lock City.

Plainfield, N. J.—The work on the extensions of the Brunswick Traction Company between Dunellen and Bound Brook are being pushed rapidly with large gangs of workmen, and it is expected that the road between those two places will be in operation by August 1. Already the line between Bound Brook and Somerville is in operation. When the tracks are laid through Dunellen they will connect with the line of the Plainfield Street Railway Company, which will give Plainfield trolley connections with New Market, Lincoln, Bound Brook, Finderne, Somerville, Raritan, New Brunswick, Franklin Park and Metuchen.

Redlands, Cal.—Ex-postmaster J. H. Boyd of San Bernardino is planning to build an electric railway from that city to Redlands utilizing the abandoned street railway line on D street in San Bernardino.

Rockford, Ill.—A deal has been closed for the consolidation of the City Railway and Rockford Traction companies, to be managed under the name of the Rockford Light & Power Company. John Farson of Chicago owned the Traction plant.

Sandusky, O.—Judge Bentley of Cleveland, representing the Cleveland & Norwalk syndicate that proposes to buy all the electric railway property in Sandusky and to build a road from here to Lorain to connect with one from there to Cleveland, purchased at public sale here on the 9th inst. the plant of the Sandusky electric street railway and is negotiating for the purchase of the other local line, known as the People's. The price paid for the Sandusky company's plant was $60,024, which was two-thirds of its appraised value.

Saratoga, N. Y.—The steam railroad which was operated to the summit of Mount McGregor has been abandoned, and the Saratoga Electric Company proposes to build an electric line over the same route, about nine miles, and over a rough but picturesque country. The trolley line now operated between this city and Saratoga Lake and to the Geysers is said to be paying so well that the company intends soon to build a road to Lake George, a distance of thirty-three miles.

San Francisco, Cal.—The San Francisco & San Mateo Electric Railway Company, the Market Street Railway Company and Oscar T. Weber and associates having filed applications for street railway franchises in the city and suburbs of San Francisco, the board of supervisors advertise a sale of the respective franchises on August 8.

Springfield, O.—It is rumored that a project is on foot to build an electric car line from this city to Yellow Springs, and that Eastern capitalists are considering the matter. There was a similar plan agitated several years ago by other parties, but the scheme fell through

St. Paul, Minn.—It is expected that the new Selby avenue electric line will be in operation by the 1st of August. The work of construction at the hill, including the placing of the new safety device, has been a difficult task. The cost per mile of laying the electric tracks and doing the work incident thereto is estimated at between $25,000 and $30,000.

Washington, D. C.—The "Star" says "it is not likely the Belt railroad will be offered for sale before the 1st of October next. No order of the court directing the sale has as yet been made. It is thought, however, as the transfer of this property, in view of the law lately enacted requiring the equipping of the road with the underground electric system within one year from the ratification by the court of its purchase, involves the outlay of considerable money, it will be necessary to fix such a time for the sale of the road as will enable prospective purchasers to make the necessary financial arrangements."

LIGHTING PLANTS.

Albion, N. Y.—The new local electric light company has a capital stock of $50,000. The directors are Frank A. Dudley, Wallace C. Johnson, a Niagara Falls engineer, Sanford T. Church and Albert Culver of this city. The fifty lights required will not be burning until October 1st, when the Waterport plant will be in operation. A dam 18 feet high is to be built and power will be supplied by 200 horse-power turbine wheels. Two 80-light arc dynamos and two 1,500 light incandescent dynamos will be put in. Until the time mentioned about 25 lights, furnished from steam power, will be in operation.

Beloit, Wis.—The Beloit Electric Light & Power Company has closed a deal whereby it becomes the owner of the Rock River Paper Company's plant, and will convert it into a first-class electric light and power plant. It is the intention of the company to give Beloit one of the most complete light and power plants in the Northwest.

Cincinnati.—The loss by the fire at the Edison Electric Light Company's power station here on the 8th inst. is much less than the first estimate. The value of the building destroyed was about $5,000 and the loss to the machinery and other contents was between $15,000 and $20,000.

East Weymouth, Mass.—John R. Graham and a number of other men have bought the plant and franchise of the Weymouth Electric Light Company in this place.

Fargo, N. D.—The council has passed the ordinance granting an electric light franchise to Gen. Hughes of Bismarck over the mayor's veto.

Fostoria, O.—The directors of the Fostoria Light & Power Company, having received an offer for the purchase of their plant from a Philadelphia company represented by S. R. Bullock of that city, will submit the matter to the stockholders at an early date.

Grand Rapids, Mich.—Mayor Perry has vetoed the municipal lighting plant contracts and new bids will be advertised for.

Lansdale, Pa.—A lot has been purchased by the town and $20,000 appropriated for the erection of an electric plant for street and commercial lighting.

Mercur, Utah.—The transforming station of the Camp Floyd Electric Light Company was struck by lightning recently and was totally destroyed by the resulting fire.

Redlands, Cal.—A transaction is under consideration whereby the San Bernardino Electric Company will come under the control of the Redlands Electric Light & Power Company. This will give the Redlands Electric Light & Power and the Southern California Company control of all lighting between Redlands and Los Angeles.

Scranton, Pa.—A movement is on foot by Scranton and Wilkesbarre capitalists to purchase all the electric light companies between Pittston and Nanticoke. There is every indication that the effort will be successful and that the deal will be consummated at an early date. There are between Pittston and Nanticoke fifteen companies, and it is asserted that all of these have been approached and terms for sale agreed upon in the majority of cases.

Somersworth, Mass.—From present indications it is safe to state that the movement in this city to establish a municipal electric lighting plant will ultimately be defeated. Many arguments for and against the project are daily heard, but the scheme is rapidly losing ground. The city councils were recently informed on the best possible authority that to establish and maintain a municipal plant it would cost the city annually $87.50 per lamp. The city is now paying $80, and it is understood in the near future this figure will be reduced.

Washington, D. C.—Proposals will be received by the District Commissioners until 12 o'clock, July 30, for lighting the public streets, avenues, alleys and roads in the District of Columbia during the year ending June 30, 1899, with gas, naphtha, incandescent and electric arc lamps. Specifications and blank forms of proposals may be obtained at the office of the commissioners in Washington.

Wooster, O.—The Wooster City Lighting Company having declined to concede the reductions asked for by the lighting committee, there is talk of the city putting in its own electric lighting apparatus. The lighting company claims that after large investment and years of hard work they are just getting the plant where it is on a paying basis, and that the town is not large enough and the number of lights required too small to warrant further concessions. The company has a perpetual franchise on the commercial lighting.

MANUFACTURING, ETC.

Ampere, N. J.—A large addition is being built to the Crocker-Wheeler Electric Company's plant in this place. The structure will be of brick and is to cost about $9,000.

Baltimore, Md.—David R. Walker, chief of the Bureau of Electricity of Philadelphia, has been consulted on the question of municipal subways. He says that they have demonstrated to the electrical companies in Philadelphia that the underground system was more economical than the overhead system. He thinks that Baltimore can make a start on the subway system with $1,000,000, and that the system can be built and operated so as to pay for itself, give revenue to the city and not be burdensome to the companies renting space.

Detroit, Mich.—The Western Electric Company of Chicago, preparatory to opening a branch establishment in this city, has filed articles of incorporation with the Secretary of State, placing its capital stock at $1,000,000.

Kingston, Jam.—The new tariff of Jamaica places electrical apparatus and appliances of all kinds for generating, storing, conducting, measuring and converting into power, light, etc., on the free list.

Louisville, Ky.—The stock of James Clark, Jr., & Co., dealers in electrical supplies, was almost totally ruined on the 12th inst. by the burning of the building in which the firm was located. Mr. Clark estimates his loss at $20,000; insurance $17,000.

Milford, Conn.—Work has been resumed at the works of the National Electrical Manufacturing Company. A number of good sized orders are said to have been received.

New York.—The Babcock & Wilcox Company will be awarded a contract from the Electric Lighting Committee of Edinburgh, Scot., for steam and exhaust pipe. The value of the contract is said to be $13,130. Everything else required by the committee will be purchased in Scotland or England.

Pittsfield, Mass.—The delicate machinery in the laboratory of William Stanley, Jr., was somewhat damaged by a fire that occurred a few days ago in the block in which the laboratory is located. The extent of the damage could not be fully ascertained as Mr. Stanley was ill at his home and could give no estimate.

Roselle, N. J.—The New Orange Company has broken ground here for a large factory for the Oxley & Enos Company of New York, manufacturers of electrical fittings.

Washington, D. C.—The Bureau of American Republics has been informed that Mr. James G. Kelley has applied to the municipality of Buenos Ayres for a concession to construct two underground electric railways in that city. The roads are to be ready for use within three years after the granting of the concession. Six per cent. of the total receipts are to accrue to the municipality. Both lines, with the entire plant and all rolling stock, shall become the absolute property of the municipality, free of any claim or compensation, at the expiration of 99 years.

TRANSMISSION PLANTS.

Canal Dover, O.—Leiser & Bowers, well known millers, have decided to build an electric light and power plant on a large scale. The plant will be erected on the site of their recently burned flouring mill on the Tuscarawas River and the water power there will be used to generate electricity. It is proposed to wire the electricity and furnish power to all parts of the county, and if subscribers in sufficient number can be secured the cost of light and power will be reduced to the minimum, and the promoters say this will be scarcely one-half the figures now charged.

Seattle, Wash.—Work is progressing on the Snowqualmie Falls electric power system, but the delay in getting a franchise from the city of Seattle is causing the company some uneasiness, and they are withholding all orders for machinery until they are assured of the council's favorable action.

COMPANY MATTERS.

Hartford, Conn.—The Bryant Electric Company has increased its capital stock from $75,000 to $100,000.

Lynchburg, Va.—A meeting of capitalists of New York and other places who are interested in the property recently purchased from the Lynchburg Electric Company, including a street railroad, will be held here on July 26th for the purpose of organizing and electing officers of a new corporation to be known as the Lynchburg Electric and Light Company.

NOTES FROM A CORRESPONDENT.

Albany, N. Y.—The survey of the Albany, Helderberg and Schoharie proposed electric road has been completed by the engineer corps under Chief Engineer H. H. Schermerhorn. Everything is being arranged so that as soon as the right of way is secured the Albany Construction Company, to whom has been awarded the contract to build the road, may be able to begin work.

Troy, N. Y.—The E. G. Bernard Company has closed a contract for electric motive power for the Washington Navy Yard.

Lansingburgh, N. Y.—The directors of the Beacon Electric Company have declared a quarterly dividend of one and one-half per cent. The proposed plan of extending the plant was left to a committee with power. The day service will be in operation as soon as the dynamos can be placed.

Schenectady, N. Y.—The General Electric Company will make this week the first shipment of the machinery to fulfill its contract with a railroad company in London, Eng. This installation is to be done by the employees of the company's English office. The locomotives to be used are similar to those used on the Baltimore & Ohio Railroad in the tunnel at Baltimore.

PERSONAL AND MISCELLANEA.

Robert T. Lee of Newport, R. I., has been chosen to fill the vacancy caused by the resignation of Mr. Townsend as superintendent of the Woronoco Street Railway Company. Mr. Townsend goes to Meriden, Conn.

Ernest Grauer, the electrician who miraculously escaped death in the explosion of the Pompton powder mills, is slowly recovering from the effects of the shock at his home in Brooklyn, N. Y. Grauer had been employed about the Pompton works off and on during the summer. He attended to the electric lighting plant and had been making some repairs to the wires just before the explosion occurred. The force of the latter hurled him against the wall of the factory office and thence back again under a table in the middle of the room, but beyond a few scratches and some severe bruises he was unharmed.

Edward Lauterbach, A. J. Dittenhoefer and Herbert R. Limburger, of New York, have issued a statement in defence of the character of Dr. Cornelius Herz, who died in Bournemouth, England, recently. It says Dr. Herz was a citizen of the United States, and though accused by the French Government of complicity in the Panama Canal scandal, was never connected with the Panama Company, financially or otherwise. The charge of extortion practised upon Baron Reinach before his death is alleged to have been trumped up against Dr. Herz in order to procure his extradition to France, and official documents are quoted to show that the charge was dismissed by Sir John Bridge, an English magistrate.

"Electric fans have probably come to stay," remarked an electrician to a Washington "Star" reporter, "and though they are decidedly pleasant to many during stuffy and very warm weather, there are some things about them that are not thoroughly enjoyable as far as after effects are concerned. My experience is that persons should not sit for any long time in the direct draught of them, especially if they are sensitive to draughts. It may not always feel so, but the fan is just as cooling if the wind produced by it does not strike you directly. Better have it strike you from either side, however, than full in the face or back, and especially avoid having it play on the back of your neck. People who are suffering from neuralgia have found this out for themselves. There is a peculiarity about electric fans, and that is that persons sitting so the wind plays on them directly in nine cases out of ten will have a slight attack of sneezing the moment they go out in the open air. If the circulation is above the head it is better than if it is on the level of your head."

The Detroit "Free Press" gives the following as "a lesson in electricity": "There was a small boy on Ledyard street Saturday that learned something about electricity in a very short time. A youngster just at the 'cute' age sat on a horse-block sprinkling the street and every now and then seeing how near he could throw a stream of water to occupants of passing carriages without hitting them. He sat with the hose under him and as an electric car approached he bethought himself of an idea. He waited until the car was almost in front of him and then turned the stream into the motor. The effect was pleasing to those who had been watching him. The instant the water struck the exposed portion of the motor the boy rose nearly a foot in the air. He let out an ear splitting yell, and dropping the hose, started as fast as his legs could carry him up the street. In that short space of time he had learned that water is an excellent electrical conductor, that electricity will follow a stream of water back to the hose, and that if anyone has hold of a brass nozzle he will get a shock."

RECENT COMPANY ELECTIONS.

Orange & Passaic Valley Railway Company, Orange, N. J.—President, Charles A. Sterling; vice-president, William Scheerer; secretary and treasurer, John H. Ely.

Cumberland Electric Railway Company, Cumberland, Md.—President, George L. Wellington; vice-president, Lloyd Lowndes; secretary and treasurer, J. H. Holzsher; directors: the officers and James A. McHenry and W. M. Roberts, Jr.

Metropolitan Railway Company, Washington, D. C.—President, Robert D. Weaver; vice-president, A. B. Grunwell. These and Nathaniel Wilson, W. B. Gurley, S. T. Brown, John Cammack, John Joy Edson and W. J. Spence comprise the new board of directors.

COMMERCIAL PARAGRAPHS.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

INCORPORATIONS.

The Framingham, Southboro & Marlboro Street Railway Company, Framingham, Mass.—to construct and operate a street railway nine miles in length. Capital stock, $120,000. Directors: S. H. Howe, F. D. Newton, C. B. Sawin, J. R. Entwistle, W. B. Ferguson, C. E. Barnes and G. A. Butman.

The Colby Electric Manufacturing Company, Chicago, has certified to a change of name to the Chicago Non-Refillable Bottle Stopper Company.

The Ballard Electric Company, Chicago, has certified to a change of name to the Wells-Goodhue Company.

The Standard Electric Repair & Construction Company, Cleveland, O.—to manufacture and repair electrical apparatus, appliances, etc. Capital stock, $1,000. Incorporators: Lewis Sands, William J. Bowen, James O. Jones, C. A. Bejock and F. B. Skeels.

The Dayton & Germantown Traction Company, Dayton, O.—to do a general passenger, freight, mail and express business between Dayton and Georgetown. Capital stock, $10,000. Incorporators: Fred Shoap, Isaac Bassett, Noah Caler, P. T. Meredith and Theodore C. Lendsey.

The Vigo Light & Power Company, Terre Haute, Ind.—to generate and manufacture electric light, heat and power. Capital stock, $50,000. Incorporators: William R. McKeen, Herman Hullman, James R., Andrew H. and James A. Crawford.

The East St. Louis & Collinsville Electric Railway Company, East St Louis—to build and operate an electrical railroad from East St. Louis to Collinsville. Capital stock, $2,500. Incorporators: William Ortgier, T. T. Ramey and W. E. Hadley.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JULY 12, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

607,065. Trolley for Third Rails. Lowell E. Maxham, Boston, Mass. Filed Sept. 1, 1897.

607,191. Trolley. William H. Russell, Chicago, Ill. Filed May 21, 1897.

607,351. Electric Railway. William W. Doty, New York, James A. MacKnight, Mount Vernon, and Charles Grauten, New York, assignors, by mesne assignments, to W. W. Doty & Co. and William Reinhart, New York City. Filed Jan. 25, 1897. Renewed Dec. 24, 1897.

607,387. Trolley for Electric Railways. Henry Van Hoevenbergh, New York City. Filed Aug. 31, 1897.

607,118. Car-Fender. William H. Martin, Los Angeles, Cal. Filed March 31, 1897.

ELECTRICAL MACHINERY AND APPARATUS.

607,036. Electric Controlling Apparatus for Switch-Valves. Elmo G. Harris, Rolla, Mo. Filed Sept. 25, 1897.

607,121. Automatic Cut-Out for Secondary Batteries. Walter L. Negbaur, Brookline, Mass. Filed Feb. 19, 1897.

607,125. Method of and Apparatus for Generating Electricity. Walter L. Negbaur, Brookline, and Joseph J. Feely, Walpole, Mass. Filed June 17, 1897.

607,176. Electric Break for Induction-Coils. Thomas B. Kinraide, Boston, Mass Filed Feb. 26, 1897.

607,177. Electric Break and Induction Apparatus. Thomas B. Kinraide, Boston, Mass. Filed July 26, 1897.

607,185. Electric Meter. William D. Marks, Philadelphia, Pa., assignor to the American Electric Meter Company, same place. Filed Nov. 4, 1897.

607,213. X-Ray Apparatus. Henry Green, Hartford, Conn. Filed Sept. 30, 1896.

607,247. Electric Motor. Warren S. Johnson and Henry Winkenwerder, Milwaukee, Wis., assignors to the Johnson Electric Service Company, same place. Filed Nov. 9, 1896. Renewed June 1, 1898.

607,250. Electric Cut-Out. Harry A. Lewis, Norristown, Pa., assignor of three-fifths to John T. Dyer, same place. Filed July 14, 1897.

607,251. Fuse-Holder, Circuit-Breaker and Lightning-Arrester. Harry A. Lewis, Norristown, Pa., assignor of three-fifths to John T. Dyer, same place. Filed July 11, 1897.

607,311. Electric-Current Controller. Ernest E. Werner, Philadelphia, Pa., assignor, by mesne assignments, to S. Eldred Gilbert and Samuel I. Shute, same place. Filed Feb. 23, 1897.

TELEPHONE AND TELEGRAPH APPARATUS.

607,239. Telegraph. Leo W. Hildburgh, New York City. Filed June 2, 1897.

MISCELLANEOUS.

607,018. Underground Electric Conduit. Thomas Connelly, Chicago, Ill. Filed Nov. 12, 1897.

607,007. Apparatus for Manufacturing Ozone. Emile Andreoli, London, England. Filed Oct. 15, 1897.

607,070. Electric Cable for Driving Conveyances. Addison Norman, Toronto, Canada, assignor of one-fourth to William McCabe, same place. Filed April 19, 1897.

607,078. Electrode-Plate for Electric Accumulators. Paul F. Ribbe, Berlin, Germany. Filed Jan. 25, 1898.

607,093. Electrically-Heated Roll. Fred P. Snow, Lynn, Mass. Filed May 3, 1897.

607,302. Electric Locomotion. Harry Van Hoevenbergh, New York City, assignor to Noah C. Rogers, same place. Filed Nov. 20, 1896.

607,315. Insulator. Charles L. Wingard, Walla Walla, Wash., assignor of one-half to Luella Hulme Wingard, same place. Filed April 13, 1898.

607,343. Switchboard and Alarm Mechanism. John P. Conway, New York City. Filed May 5, 1897.

607,407. Alarm System. Clyde Coleman, Chicago, Ill., assignor, by mesne assignments, of two-thirds to George P. Jones, same place. Filed Oct. 18, 1897.

RE-ISSUE.

11,678. Electric Signaling Mechanism. Lewis G. Rowand, Camden, N. J. Filed Dec. 15, 1897. Original No. 593,692, dated Nov. 16, 1897.

DESIGN.

29,046. Electric-Light Sign. Mortimer Norden, New York City, assignor to Joseph Norden, same place. Filed May 16, 1898.

TELEPHONE AND TELEGRAPH.

The hearing in the suit of the Western Electric Company of Chicago, to restrain the Detroit Telephone Company from using certain devices which, it is claimed, infringe the patents held by it and the Bell Telephone Company, was resumed before Judge Swan at Detroit on the 13th. The "busy" device, by which the telephone girl is enabled to tell whether a line is in use or not, is the only patent under discussion. It was argued by the defence that it would be an injustice to grant the temporary injunction, especially as some of the patents expire in six months and numerous electrical experts had testified that there was no infringement. It was also urged that in view of the extensive use of the new telephones in Detroit and elsewhere any interference with their operation would be a hardship to the people that the facts in the case would not warrant.

Contracts are being made by the Bell Telephone Company of Missouri with St. Louis druggists for the placing of automatic telephones in their places of business. The subscriber agrees to collect tolls to pay to the company, and in full of compensation the company agrees to pay the subscriber a commission of 10 per cent. on all receipts for messages sent from each station to some other station in the cities of St. Louis or East St. Louis, connected with an exchange of the company, and also on long distance messages. The company will attach to each 'phone a coin-receiving device for messages, the same as are now in operation in other cities. It is stated that the machines in question have been shipped to St. Louis, and will be in operation not later than August 15.

Notice of the signing of a contract by the Executive Council of the Hawaiian Government granting the right to lay a cable between Hawaii, the United States, Japan and China to the Pacific Cable Company of New York, was received at the office of the company in New York last Thursday. This news, according to the *Herald*, was contained in a despatch from W. G. Irwin, Honolulu, forwarded by wire from Victoria, B. C., which said that the contract was signed on July 2, and that it grants exclusive cable rights between Hawaii, Japan and the necessary islands in the Pacific Ocean for twenty years. The directors of the Pacific Cable Company are James Scrymser, Edmund L. Baylis, Admiral John Erwin, J. Pierpont Morgan and J. Kennedy Tod. Mr. Scrymser is its president and Mr. Baylis its vice-president. Its capital is $10,000,000, and it was incorporated under the laws of New York.

The Philadelphia councils have finally passed the ordinance granting permission to the Drawbaugh Telephone Company to establish a service in that city in opposition to the Bell Telephone Company's business. The first application for the privileges granted was made as far back as 1884, but was so loaded down with conditions that successful competition against the Bell service would have been impossible. The new company is also considerably restricted. It must pay the city 3 per cent. of its gross receipts, give a bond more than twice as large as the Bell Company, and charge a maximum of $75 per annum to subscribers. The Bell Company now charges what it likes, and the cost is at present $120 per annum.

The Iowa Telephone Company has threatened the city of Des Moines with a lawsuit to test the right of the city to prevent its use of the streets, alleys etc., for the erection of poles and wires required in its operations. The council in passing the ordinance depriving the company of these privileges took the ground that the company had no franchise and was therefore an interloper. The telephone company takes the position that the city has been tardy in finding this out, has permitted the company to prosecute the work of building and operating an exchange, and that as a result it has a vested right of which it cannot be deprived.

Bonds of the Cumberland Telephone & Telegraph Company are being offered in Boston by Parkinson & Burr. The company is capitalized for $3,000,000 stock ($2,875,000 outstanding) and has a bonded indebtedness of $1,000,000 In March last the company absorbed the Great Southern Telephone Company, and is stated to have now 16,000 exchange stations under its control. It operates through the southern portions of Indiana and Illinois, the western portions of Kentucky and Tennessee and the entire States of Mississippi and Louisiana. It is a Bell licensee company.

The St. Paul board of aldermen has passed a resolution naming the streets that can be used by the Mississippi Valley Telephone Company. There was some doubt as to whether the company had not forfeited its franchise by its tardiness, but on being assured that it had really begun work the aldermen passed the resolution referred to by a unanimous vote.

A press dispatch from Des Moines states that a movement is on foot for the consolidation of all independent telephone toll lines in Iowa under one management and the merging of the several companies into one big organization. Propositions for the proposed consolidation have been forwarded to the management of a number of lines, with every indication that they will be accepted, and that a meeting to outline the plan of consolidation will be called in Des Moines at an early date. The nucleus will probably be the Central Telephone Company of Des Moines.

We learn from a Boonville dispatch in the Utica *Observer* that arrangements are about completed whereby the Boonville Telephone Company, which obtained a twenty year franchise, gives up all its right, title and interest to the Central New York Telephone Company, which has done some wiring and expects soon to have an exchange in operation. The consideration is not known, but it is reported that the Central Company takes the pole and telephone apparatus which the Boonville Company had purchased with the idea of starting an exchange.

A new telephone combination has been formed at Greenville, S. C. George A. Browning, president of the Green ville Home Telephone Company, and his associates have organized the Piedmont Telephone & Telegraph Company. The new company will have exchanges at Anderson, Abbeville, Greenwood, Laurens, Alston, Newberry, Gaffney and Spartanburg and intermediate points. These exchanges will be connected with metallic circuit and long distance 'phones.

The Mamaroneck, N. Y., trustees have received an application from George W. Sutton, of New Rochelle, to establish a local telephone company. Telephones are to be rented for $36 a year, or $3 a month, and the village is to have the free use of two instruments and the poles for a fire-alarm system. The application was referred to the corporation counsel.

The city council of Lexington, Ky., has passed a resolution authorizing the Mayor to enter into a contract with the East Tennessee Telephone Company for the grant of a telephone franchise for twenty-five years at an annual rental of $1,200. The Standard Telephone Company was the only competing applicant for the franchise, offering a number of free 'phones to the city and an annual payment of $500.

J. A. Helvin, the promoter of the proposed underground telephone system at Chattanooga., Tenn., who is recovering from a critical illness, is expected at Chattanooga this week. He is said to be sanguine of the success of his telephone enterprise, for which, it will be remembered, he secured a franchise a few weeks ago.

The American Telephone & Telegraph Company has moved its division headquarters from Cincinnati to St. Louis, and this is considered as an indication that St. Louis, which was formerly only a station in the district, handled from Chicago, is to become a telephone center.

The police and fire department wires at Syracuse, N. Y., will be placed in the Central New York Telegraph & Telephone Company's subways. The company has reserved a duct in its subways for the free use of the city.

The Mutual Telephone Company of Des Moines has determined to put in a new switchboard to accommodate 1,500 patrons. Its present board is only fitted for 800, and the business demands increased capacity.

It is stated that the large demand for insulated wire for Government uses has delayed the work of the Kinloch Telephone Company at St. Louis, and will prevent the opening of the lines at the time expected, August 1.

A telephone exchange is being erected at Eatonton, Ga., by E. H. Davis, the city superintendent of waterworks, who will be the manager. Connections with the larger cities of the State will be made as soon as the exchange is on a solid working basis.

The Crescent City Telephone Company has made a proposition to the council of Evansville, Ind., to put in a first-class telephone exchange in that city if granted a franchise.

The Red Wing Telephone Company, composed of H. L. Sumptur and Irving Todd, Jr., of Hastings, has been granted a telephone franchise by the city council of Red Wing, Minn.

Tishomingo, I. T., is now connected with the outside world by telephone, the line from Ardmore having been completed and a 'phone put in at the Chickasaw capital.

A telephone cable has been laid between Block Island and Narragansett Pier.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by Electricity from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 11⅜@11½c.; Lake, 11⅝c.; casting, 11⅛@11¼c.

The Central Printing District Telephone Company has declared a regular quarterly dividend of 2 per cent., payable to stock of record July 14.

The United Electric Securities Company, Boston, has retired the following bonds: Seventeen, series 5, at 99.19; 110, series 8, at 102.25; 112, series 9, at 102.06.

The Albany (N. Y.) Railway Company has declared the regular quarterly dividend of 1½ per cent. and an extra 1½ per cent., payable August 1 to stock of record July 21. Books open August 2.

The Edison Electric Illuminating Company of New York reports for June: Gross earnings, $215,156; operating expenses, $135,721; net earnings, $79,435, an increase of $16,230 over the net earnings for the same month in 1897.

Justice Dickey of the Supreme Court of Brooklyn has appointed J. Van Smith receiver of the Staten Island Rapid Transit Company. This is in line with the reorganization of the Baltimore & Ohio, of which system the Staten Island road is a part.

The New England Telephone & Telegraph Company of New York filed on the 14th inst. with the Secretary of State at Albany a certificate of an increase of its capital stock from $12,000,000 to $15,000,000. The debts and liabilities of the company amount to $3,505,404.

It is announced that the Westchester & Connecticut Traction Company has purchased the North Mount Vernon Railway Company's property and proposes to build a trolley road from Mount Vernon through Bronxville, Tuckahoe, Scarsdale and Hartsdale to White Plains.

The Consolidated Street Railway Company of Atlanta, Ga., is about to refund its 5 per cent. bonds at 4 per cent., and a proposition to this effect, says the "Journal," based on a surrender of a part of the stock to the bondholders, has received the assent of two-thirds of the parties interested.

The directors of the Edison Electric Illuminating Company of Boston, at their meeting on the 14th, declared quarterly dividend No. 37. They made it 2 per cent., payable August 1 to stockholders of record July 15. This is an increase of ½ of 1 per cent. over recent previous payments.

The amalgamation of the Municipal Electric Light Company with the Edison Electric Illuminating Company of Brooklyn has been completed, and substantially on the basis outlined in the circular issued by the Municipal Company to its stockholders on June 20. All or nearly all of the 75,000 shares of stock of the Municipal Company has been transferred.

The special meeting of Metropolitan Street Railway stockholders called to vote upon a proposition to increase the capital stock will be held in New York on August 9. The resolution offered will be to make the stock $45,000,000 instead of $30,000,000 as at present, an increase of $15,000,000. Ten million dollars of this sum is to be sold to the stockholders at par on the terms heretofore outlined, while $5,000,000 will be retained in the treasury.

The Appellate Division of the Supreme Court in Brooklyn, N. Y., has affirmed the judgment of the lower court upholding the traffic agreement by which the Brooklyn Heights and the Brooklyn City & Newtown Railroad companies have been using the trolley line tracks in Washington street. The plan was inaugurated when the bridge trolley system went into effect, and is intended to relieve the congestion of traffic in Fulton street.

The Metropolitan Street Railway Company, New York, has given public notice that it will, on July 20, begin the electrical construction on the Sixth and Eighth avenue lines south of 59th street, and that during such work the horse car lines on those avenues will be discontinued. In the meantime it will give its patrons extra facilities in the way of transfers, including east and west transfers.

On the 13th inst. all the property of the Columbia & Maryland Railroad Company was formally transferred to the Security & Trading Company and the $450,000 purchase money handed over. The company has now been divided into two lines, the Maryland Traction and the City & Suburban Railway Company controlling respectively the Washington and Baltimore branches. The Consolidated Railway Company of Baltimore has arranged to purchase the line between Baltimore and Ellicott City.

The assets of the Kings County Traction Company, consisting of 39,987 shares of the capital stock of the Atlantic Avenue Railroad Company of Brooklyn, N. Y., and the options upon the remaining thirteen shares of said capital stock, and options upon nine shares of the capital stock of the Brooklyn, Bath & West End Railroad, were sold at public auction on Thursday last for $2,100,000. The purchaser was E. H. Harriman, representing the directors of the company.

Judge O'Rourke, of the Circuit Court at Fort Wayne, Ind., on Wednesday last rendered a decision finding that John J. Shipherd, the Cleveland (O.) financier, had wrongfully appropriated, by himself and through banks, $990,000 worth of bonds of the Fort Wayne Consolidated Street Railway. The effect of the decision is to turn back into the assets of the company, now in the hands of receivers, that amount of bonds, to be used in paying legitimate liabilities. The Guardian Trust Company of Cleveland and banks of that city were the principal defendants, and they will attempt to get a new trial.

A dispatch from Schenectady, N. Y., states that the directors of the General Electric Company have issued a call for a meeting of stockholders, to be held in that city August 10, for the purpose of voting upon a proposition to reduce the capital stock of the company from the present amount, consisting of 304,600 shares of common stock of the par value of $100 each, and 42,520 shares of preferred stock of the par value of $100 each, to $20,827,200, which is to consist of 182,760 shares of common stock of the par value of $100 each, and 25,512 shares of the preferred stock of the par value of $100 each. The meeting, it is said, will be the most important ever held by the company.

The deal whereby the Kings County Electric Light & Power Company will absorb the Edison Electric Illuminating Company of Brooklyn is confirmed in a circular sent out on Saturday last by President Ethan Allen Doty of the Edison Company. The matter will be submitted to the stockholders of the companies as soon as the papers are prepared. The stockholders of the Edison Company will have the right to subscribe for 25 per cent. additional stock at par, and for the whole amount of stock they will then be offered par price in ninety-nine-year 6 per cents. Purchase money mortgage bonds will be secured by the deposit of the Edison stock so sold and additionally by a junior mortgage of the Kings County Company upon its property and further by the deposit of a guarantee fund of $1,000,000.

The Philadelphia "Stockholder" says, under the heading "When the War Ends": "This country seems ripe for a great expansion in business and the growth of new enterprises. The war with Spain, when it shall have ended, will, as the outlook now presents itself, add to both the glory and the confidence of the American people. There will be the incentive to activity which comes from consciousness of strength coupled with ambition. But not only is the incentive present, but there is also the money. Not in the financial history of the country has there been such an extraordinary amount of surplus funds. There will be money for all reasonable ventures, and some that are not reasonable, when the opportunity for lending at profitable rates has passed, as it will pass, with the restoration of peace."

EDITORIAL NOTES.

Insulators. As is well known, the insulating power, or more properly speaking, dielectric strength, of any material with reference to a given current depends to a great extent upon the tension or energy of that current. This is essentially so in the case of insulation for conductors such as are found in the coils of high potential transformers. In the case of outside insulation however, where a conductor several miles in length carries a current of extremely high tension, the shape of the insulator plays an important part. Since the introduction of high tension transmission, or where a line transmits current at a pressure of from 10,000 to 20,000 volts, this question of properly insulating the conductor from its supports has become an exceedingly important one. Glass or porcelain has to be relied on almost entirely, although in some cases pottery or stone ware insulators have been used in foreign countries. None of these substances are by any means ideal, and especially glass, which is too brittle and very apt to be broken under a jerk or strain. One of the principal reasons apparently why glass is so extensively used on telegraph and other low tension transmission lines in this country at the present day is owing to its cheapness, and to the fact that for some unaccountable reason porcelain insulators in rural districts are said to be much sought after by certain insects who take up their abode under the hood and spin webs, and thus by connecting the insulator with the cross-arm offer in damp weather a path of escape to the current.

Owing to the brittleness of glass, so far on most of the very high tension transmission lines in this country porcelain is used. An early type of such insulator closely resembled in appearance a student's lamp shade, but these ultimately were done away with, as it was found that the drip from the outside of the insulator fell on the cross arm, and in case of a very heavy rain made a continuous stream which entailed an appreciable loss of current and frequently destroyed the insulator through overheating. With a view to overcoming this serious defect, what is known as the "helmet" type of insulator was brought out. This is oval in shape and so designed that all the drip in wet weather falls from two ends that hang out several inches from the cross-arm. Another form of porcelain insulator recently patented and intended for potentials ranging from 5,000 to 50,000 volts, is made in three separate parts fitted one into the other and fused together with glaze, the inner part being provided with a socket by which it is mounted. In this type of insulator the inner shell extends down to a point adjacent to the cross-arm, and forms a sleeve for the purpose of protecting the pin from static discharge or leaking of the current around the insulator.

On all telegraphic lines where glass or porcelain insulators are used there is, as is well known, always more or less leakage due to the insulator becoming damp through the condensation of the moisture of the air. In the case of a high potential transmission line, however, this accumulation of dampness on an insulator does not, as would naturally be inferred, cause a leakage providing the insulator is properly shaped. This is due to the fact that as soon as an insulator on such a line becomes moist and leakage tends to begin, static electricity is immediately formed, which heats the surface of the insulator and preserves comparatively large dry areas between the streams that run down from the falling drops.

This remarkable action of the drying of porcelain insulators by static electricity is probably one of the most valuable discoveries so far noted in the transmission of high potential currents.

The Nernst Electric Lamp. Dr. Johannes Horowitz, in a recent communication from Vienna to the New York *Times*, referring to the new electric lamp invented by Prof. Walter Nernst, makes the interesting statement that although all the rights and patents have been acquired by a Berlin syndicate at a price of 6,000,000 marks, or $1,-500,000, no practical or commercial use can as yet be made of the discovery. As we stated some time ago, in the Nernst lamp the carbon filament is entirely done away with, a conductor or filament of magnesia or other metal oxide that has been subjected to an intense heat being substituted. Referring to the metal oxides, Dr. Horowitz in his communication says:

"When in a conducive state such bodies allow the electric current to pass, and through it they are made to glow intensely by reason of the great light-emissive power possessed by the substances. Nernst's incandescent bodies have proved perfectly stable at the enormous temperature (more than 300 degrees centigrade) which is produced by electricity when these bodies are made to glow, a temperature at which platinum wire and carbon filaments become volatile and waste away. This renders it possible to produce a high degree of light intensity by means of a comparatively weak electric current, and the experiments already made have proved that we can reckon on an economy far surpassing that of the carbon filaments hitherto used. Unlike the ordinary incandescent lamp, the Nernst lamp will not require a vacuum, but will shine in the free air; indeed, the admission of air has proved to be advantageous, probably because the chemical changes brought about by the enormous heat, and especially the reduction of the incandescent substance, is compen-

sated when oxygen is taken from the air as a substitute."

Owing to a fear that electrolytic action would attend the use of the direct current, stress is laid in the patent specifications on the use of alternating currents. The Nernst lamp would seem to be a decidedly new departure in the field of electric lighting, and the further experiments that will necessarily have to be made along this line before this form of lamp can be utilized commercially, will unquestionably be watched with interest by the scientific world.

Atmospheric Electricity to Propel Street Cars?

Vol 14. p. 81,

Dr. William M. Gross of Gillespie, Ill., with his startling theory as to electricity, which we referred to at some length in an editorial in our issue of February 16, has again cropped up. He now proposes to build a tower 100 feet in height at Gillespie through which a wire about one-half inch in diameter will run. At the upper extremity of this wire a bunch of smaller wires will be attached by means of which he proposes to collect the electricity in the air. At the base of the tower will be located a machine, which the inventor calls an induction generator, to divert the current and prevent it from passing into the earth. The details of this generator have been kept secret, the visible feature however being a revolving disk two feet in diameter, which, according to the inventor, must travel in the reverse direction proportionally faster than the earth. It is Dr. Gross's opinion that enough electricity can be secured by one induction generator from the atmosphere to run a whole street-car system. As stated in our previous editorial, Dr. Gross is working upon the theory that electricity is dynamic and not static. The St. Louis *Post Dispatch*, which by the way seems to be the Doctor's mouthpiece, quotes him as follows:

"Static electricity belongs to bodies at rest. Its nature is to rise to the highest point upon the body. Dynamic electricity belongs to bodies in motion.

"The polar diameter being less than the equatorial diameter of the earth, its excess of electricity would blow off at the equator instead of at the poles, and we would no longer have the Northern and Southern lights.

"What probably occurs is, that as these currents pass around the earth through the atmosphere, they come in contact with dry areas, and as a dry atmosphere is a poor conductor of electricity it appears as a static charge and has been misleading to electricians.

"The earth and its atmosphere is the armature, and that portion of space between the earth and the sun is the electro-magnet of nature's grand dynamo-electric machine.

"The sun is shining on one-half the earth all the time. Its rays being vertical over some point of it at every instant, currents of electricity are induced out of that portion of space between the earth and the sun by the earth in its revolution from west to east. In accordance with the natural law governing electric currents, they go in an opposite direction, or from east to west.

"Lenz in 1833 demonstrated by a series of experiments that induced currents always go in the opposite direction to the electro-magnetic force producing them.

"These currents are brought down to and forced into the earth by its centrifugal force, which tends from its center toward the east, while the currents tend to its center and toward the west. When the center of the earth becomes surcharged with electricity, it flows off again at about the 70th parallel, producing the Northern and Southern lights.

"My machine is designed after the earth as a pattern. When placed at any point upon the surface and driven as required, it will be the earth's superior in centrifugal force and magnetism."

Dr. Gross's idea of collecting atmospheric electricity by means of a high metal rod is by no means new, as the French have been using in rural districts what they term a geomagnetifere, which consists of a high pole surmounted by a crown of copper spikes to which a suitable wire conductor is attached, for collecting and distributing atmospheric electricity to vegetables and plants. The amount of electricity collected by this means, however, is comparatively small under ordinary atmospheric conditions, and it is therefore rather difficult to see how Dr. Gross, in spite of his lengthy explanation and specially designed induction generator, proposes to obtain enough electricity from the atmosphere to propel a dozen or more electric cars. His experiments are worth watching however, owing to their being based on theories radically different from those generally admitted.

Probable Effect of the Omaha Exposition.

From all accounts the Trans-Mississippi and International Exposition, now being held at Omaha, is not suffering, as might be supposed, from lack of attention as a result of the war in which this country is at present engaged, as large numbers of people from all parts of the United States visit the Fair daily and display great interest in the exhibits, and especially those to be found in the electrical section, containing as they do a great variety of the latest and most useful inventions in this branch of industry. That this, the first Exposition of the kind to be held west of the Mississippi River, has so far proven an industrial and commercial success, with every prospect of proving a financial one likewise, cannot be doubted, and speaks well for the perseverance and executive abil ty of the promoters who could conceive and carry out such a gigantic undertaking during a time of more or less financial depression such as has been experienced the last few years. They are certainly deserving of great credit.

The importance of this Exposition from an educational and commercial standpoint cannot be overestimated, as a special congress has been appointed to look after the former, while as to the latter it is beyond doubt that the practical result of the Exposition will be to increase the prosperity of the Trans-Mississippi States by prominently bringing their products to the notice of the other States of the Union as well as to many European and South American countries. In other words, this Exposition should do for the Trans-Mississippi States what the New Orleans, Atlanta and Louisville Expositions did for the Southern States, and what the Columbian Exposition did for the States of the middle West.

Under the Searchlight.

Notes and Comments on Various Topics.

How the Preferred Stockholders Now Look At It.

The Boston *News Bureau* of July 19 says:

A preferred stockholder of the General Electric Company who objects to the acceptance of the plan recommended by the directors for the adjustment of the capital impairment question, says that by the adoption of the 60 per cent. reduction plan, preferred stockholders' dividends to the amount of $119,056 per annum are transferred to the common stockholders. He arrives at his figures in this way:

7 per cent. dividends on present outstanding pfd. ($1,252,000)	$297,640
7 per cent. on pfd. stock reduced to 6 per cent. ($2,551,200)	178,584
Diverted dividends	$119,056

Charles Barrett, in *New York Stockholder*, says: "The preferred stockholders are called upon to actually surrender 40 per cent. of their interest. The common stockholders surrender practically nothing. Their proportionate interest in the property and earnings of the company remains unchanged while its value is increased by the amount surrendered by the preferred stockholders.

"The right of the preferred stockholders to 7 per cent. cumulative dividends in priority to any dividends on the common stock is an individual right attaching to the stock under a contract recognized by the company and executed up to July 1, 1893. The obligations of the contract cannot be impaired, nor in any way affected by action of the corporation, taken in the only way in which a corporation can act—to wit, by vote of a duly called meeting of stockholders. Were it otherwise, the company might vote to reduce the preferred stock 100 per cent. and so get rid of it altogether; and if it had any troublesome income bonds it might dispose of them by the same process."

We are glad to see that the stand ELECTRICITY has all along taken regarding the proposed adjustment of the capital impairment of the General Electric Company is beginning to bear fruit, and the preferred stockholders are realizing that the plan suggested throws the whole burden of the readjustment upon them and leaves the common shareholders if anything better off than before. As we have repeatedly reiterated, were we a preferred stockholder we should strenuously object to the plan suggested.

The Electric Belt.

O where is the genius that promised so glibly
  To place round the earth an electrical belt,
And thus turn the globe at his pleasure? Where is he,
  In these days when humanity's ready to melt?

The belt, is it ready to turn at our pleasure?
  If so give a twist, or a button press, pray,
And give us a swing into cold, polar regions,
  Not forever, but simply an hour or two, say.

In this age Electric, with wonders about us,
  Why, why should we swelter and suffer with heat?
O, why in the world don't those bright electricians
  Bring the scheme to a head and the circle complete?

The Government, mayhap, might give them the contract
  To furnish the weather—a trust might control—
When cold they could give us a turn toward the tropics,
  When hot give excursions free up to the pole.

Cohoes, N. Y. FRANCES V. HUBBARD.

* * *

THE Boston *Commercial Bulletin*, in some comments upon the circular issued by the directors of the General Electric Company, says: "The noteworthy feature of the document, however, is the cool manner in which it is acknowledged that the General Electric Company has been carrying its patent valuation at twice its value on the books all these years. If the patent account is admitted to be excessive and can be arbitrarily cut down 50 per cent., how can stockholders tell whether the actual value is worth even a million? This is one of the evils of corporation bookkeeping. These items, as patents, franchises, etc., are given any valuation that may be convenient, and when the corporation falls into trouble or hard times, stockholders wonder where the big deficit in the balance sheet came from so suddenly. Such valuations, as in this case of the General Electric, are very apt to be utterly fictitious."

* * *

IN spite of the edict forbidding the installation of electric lights or telephones in the Sultan's realm—at least so far as European Turkey is concerned—the Commander of the Faithful himself seems vastly interested in electrical matters. He also indulges in what he denies, up to the present, to his more or less faithful subjects. The Sultan's palace is magnificently lit by electricity, and the electric boat on the artificial lake in the palace garden is daily patronized by his Majesty. A paragraph in the *Electrotechnischer Anzeiger*, referring to a recent dinner at the Yildiz Kiosk, states that the Sultan asked the German Ambassador repeated questions referring to electric lighting, and that he appeared particularly interested in the mode of power transmission as applied in the Lauffen-Frankfort station. Perhaps, says the *Electrical Engineer* of London, we may soon hear of Turkey being thrown open to electric enterprise, a field which should pay, as lavish expenditure for anything that glitters, and especially for anything that is new and Western into the bargain, is the main characteristic of the Oriental.

AN INSTANTANEOUS SPEED INDICATOR.

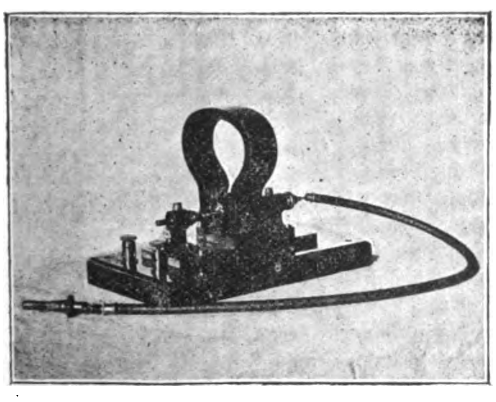
BY WM. HAND BROWNE, JR.

The following instrument, which has been used in the Electrical Engineering laboratory of the University of Nebraska to indicate speeds, has given such general satisfaction that it deserves some notice.

The instrument is, in brief, a small permanent magnet dynamo with a drum-wound armature. The field magnet is one of the standard magnets used in the Weston instruments. The armature is very carefully laminated. Flat side-bearing copper brushes are used. These permit the armature to revolve in either direction, and are adjustable around the commutator.

The armature is held in a fixed position in relation to the fields by set collars. This is necessary as any longitudinal motion of the armature would affect the readings. The instrument is used in connection with a high resistance voltmeter, and is driven directly through a flexible shaft by the machine whose speed it is desired to measure. Since the field is constant and there is little or no armature reaction, if the brushes are properly set, the EMF. generated will be directly proportional to the speed.

The instrument is herewith illustrated. Clamped to the end of the spindle will be seen the flexible dentist shaft which drives the armature. This is



sufficiently long to remove the indicator from the influence of the fields of the machine under test.

At the other end of the shaft is the coupling for attaching to the driving shaft. This is a split pin, roughened on the sides, and is simply pushed into a hole drilled in the end of the shaft. This simple device prevents all slipping and can be attached or removed while the driving shaft is in motion. The only preparation needed for the use of the indicator is the drilling of a five-sixteenths inch hole in the end of this shaft.

In determining the speed characteristic curve, a shunt motor, having a heavy fly-wheel, was driven from storage batteries to minimize the effect on the speed of fluctuations in EMF. This motor drove through a round belt and grooved pulleys the indicator, which was itself directly connected to a chronograph. Then by varying the applied EMF. any desired speed could be obtained. There was a slight drop at the upper end of this curve as the brushes were not exactly in the correct position. When this is secured, the brushes can be clamped and the characteristic is practically a straight line whether the armature revolves right-handedly or left-handedly.

By using a voltmeter having the proper amount of resistance, the indicator becomes direct reading. Otherwise the readings in volts are multiplied by a constant to ascertain the speed. The voltmeter used has a 15 volt scale and can be read to one-tenth of a division, or one revolution in 1,500.

This instrument has been in constant use for the past nine months. It is not affected by the proximity of large masses of iron. Neither the commutator nor brushes show any appreciable wear. The armature is quite cool after running steadily for two or three hours. The bearings are large and self-oiling and require no attention whatever. The whole workmanship and finish of the machine is excellent, and fully up to the high standard of the Weston Electrical Instrument Company, by whom it was made for Prof. R. B. Owens. It has proved to be one of the most valuable additions to our laboratory, and we propose adding several more to our equipment next year.

SWITCHBOARD APPARATUS.*

BY J. R. BLAIKIE,

Chief Assistant Electrical Engineer, Bristol, Eng.

The control and measurement of electric energy is one of the most fascinating details of this branch of engineering.

The switchboard, with its glittering array of polished metal and graduated dials, has always an attraction for the lay mind, while its intricacy or beautiful simplicity is a source of wonder or poetic appreciation to those better acquainted with such devices.

Almost every station has some noticeable peculiarity with regard to its switch gear, and there are few stations that have not lived to see radical changes brought about in this portion of the original scheme. The result at the present time is, that it is almost impossible to classify the types now in use. This striking non-conformity, although intensely interesting, is not particularly happy, since it appears to show either ignorance or vanity on the part of the designers.

One must admit that the spirit of commercial industry is to suppress varieties in favor of a standard. It would be ridiculous to suppose that the mere straining after novelties has been the whole cause of the present multifarious assortment. Switchboards have been conscientiously designed and constructed to suit individual cases, simply because there was no general standard that might be adopted. After certain results and experiments, modifications and improvements have been gradually introduced. But this form of private research work is too frequently misguided and uneconomical. The experimenter cannot, as a rule, afford to test a portion of his work to destruction, so long as it answers his immediate purpose he is satisfied.

A certain elegance of variety and some treasures of ingenuity must be sacrificed to further the march of scientific progress. One must be content to labor in a vast organization and strive towards a higher ideal than a more or less original switchboard. It is hard for a young enthusiast to surrender an opportunity for displaying a capacity for design in a field of such unlimited possibilities. It is far easier for him to imagine that there are peculiar necessities and requirements in the case under consideration, but seeing that there are life risks, and that the very heart of the undertaking lies in the switchboard, surely it should be the outcome of the strongest possible combination of experience, and beyond the reach of individual fancy.

Before dealing with the disposition of the component parts of the switch gear, it might be well to inquire into the duties and characteristics of the details.

The necessity for ever breaking a circuit while carrying much energy is not universally granted. For example, Prof. Forbes in his paper on "The Electrical Transmission of Power from Niagara Falls," November 9, 1893, says: "I hold that it is a piece of culpable ignorance, ruinous to the machinery, if anyone should ever on a large power circuit with alternating current suddenly break the circuit while current is passing. The practice is quite unnecessary and has given rise to a large proportion of the breakdowns of alternating current machinery." Nevertheless there are switches at Niagara (see *Cassier's Magazine*, page 291, Niagara number) capable of breaking 5,000 horse power without damage to themselves, etc. Prof. Fleeming agrees with Prof. Forbes, but he asks what happens if the circuit opens itself, and what is to be done about fuses. Unfortunately Prof. Forbes omits these points in his reply.

In practice, of course, one never opens a circuit conveying much energy unless some unforeseen circumstance throws the whole or a portion of the machinery out of the usual control. Could not such emergencies be met by inserting a moderate amount of resistance or impedance in the circuit, increasing either by degrees if necessary? The same might apply to cut-outs when they are under the observation of an attendant. In the author's opinion main switches should work through steps in this manner, making it impossible to make or break with large currents.

Assuming, as is customary, however, that a sudden break is necessary, or that the switch is in such a form that a sudden break could be made by a mistake or accident, on the part of the attendant, while transmitting a large amount of energy, the essential characteristics of the design appear to be as follows:

1. That there shall be no danger to the operator, either by electric shock or from particles of molten metal flying free, this latter to apply to adjacent apparatus as well.
2. That there shall be no maintained arc.
3. That the contacts shall not be burnt or injured in such a manner as to prevent the efficient working of the switch on closing again.
4. That the contacts and current carrying portions of the switch shall always be in such condition that no heating will occur while carrying the maximum current for an indefinite period.

With reference to the first condition there are several well known satisfactory examples. The plug form having a large insulating handle and shield, the breaks being in earthenware pots, gives a pretty certain immunity from danger. A sufficiently long handle or mechanism actuated by cords can be considered safe.

Another method is to mount a plate-glass screen between the operator and the breaking contacts, but this does not protect the other apparatus.

To secure a certainty of break many contrivances have been devised. The simplest means is a sufficiently long air gap in the circuit.

For the sake of eliciting the opinions of the gentlemen assembled, some breaks (total length) for various conditions are suggested, assuming that the breaks are made with considerable and uniform rapidity:

Amperes.	100 to 300 volts alternating or continuous.	500 to 1,000 volts continuous.	2,000 volts alternating.
5	3/4"	4"	4"
25	1"	6"	6"
50	1 1/2"	8"	10"
75	1 3/4"	10"	12"
100	2"	12"	13"
150	3"	12 1/2"	14"
200	4"	13"	15"
300	5"	14"	16"
400	6"	15"	18"
500	7"	16"	20"

(When these breaks are in the tubes, and so protected from air currents, it might be well to add, say 50 per cent. to the length of the gap, and the same if the breaks are in a vertical direction.)

The air gap may be in one line, but in order to save space and insure a rapid break, it is more frequent to have several breaks made simultaneously in a circuit. It is not safe, however, to draw out two or more arcs, close together in air, without a substantial fireproof insulator between, as a slight current of air will blow them together and thus defeat the action of the switch.

The plug switch becomes rather too cumbrous in large sizes since the sockets must be very deep or the plugs must be spaced out considerably.

One very happy solution is the use of an [electro

* Read before the Municipal Electrical Association, London, June, 1898.

magnet in the main circuit to blow out the arc when it is formed. Another effective, though perhaps rather complicated means, is the application of a shutter, or clapper, which flies through the path of the arc and blows it out with the air currents set up. Some other designs cause the circuit to be broken under water, or an insulating oil, but to the author this appears to be a last extremity as there are obvious objections to the use of a liquid.

To satisfy the third condition, "that the contacts shall not be burnt, etc.," is a comparatively simple matter. The rate of breaking is a primary consideration, though it may not apply so forcibly in the case of the alternating currents. The use of springs or the multiplicity of simultaneous breaks suggests itself at once. A liberal weight of metal, or the proximity of a good heat conducting fireproof insulator, reduces the temperature of the arcing points somewhat. As an extra precaution, the blades are usually made of wedge shape, and plugs are tapered, so that they may clear themselves more or less on returning by shearing off the small globules of metal left on the contact faces. It is therefore desirable that the mechanism should be able to withstand such strains, and so proportional that sufficient force can be applied. Another way of overcoming this difficulty is to provide auxiliary contacts which break just after the main contacts, and so carry the arc. These contacts may be merely butting surfaces, which are not much the worse for being burnt or provided with easily renewable faces, or some material having a high melting or volatilizing point, such as carbon.

The degree in which the various switches on the market meet this requirement is readily seen.

The current carrying capacity of the contacts is of the greatest importance, since a defective contact deteriorates at a sort of compound interest law. Taper plugs and spring jaws almost invariably share this responsibility. When one reflects that trouble from this source may loosen the whole contact from the board, by destroying an ebonite bush, melt the solder from a sweating thimble and allow a cable to fall, or even render the handle of the switch useless or unsafe, there is enough material for serious thought. In addition to this there is not a very far remote chance of fire. Possibly there may have been few accidents up to the present time from this cause, owing to the newness of the apparatus, or from the fact that many switches are not working up to their full capacity. Certainly in point of design this is one of the weakest features. In some nstances, the spring in cast brass and copper, without any means of adjustment for wear, is all that can be relied upon. In the case of four plugs rigidly fixed to a handle there are instances where they are supposed to go tight home into four *fixed* conical sockets. There are a few relics of the dark ages, when current was allowed to pass through the hinge or pivot of a switch. Of course there are contacts of the laminated type, built up of hard drawn or hammered copper, which are admirably suited to their purpose. As a general conclusion, under this heading, it appears that it is advantageous to have few, preferably only one, breaking contacts in a circuit, which can easily be arranged by means of flexible connections. This arrangement gives the operator an opportunity of feeling the condition of the spring contact while forcing the switch home.

It has occurred to the author with reference to this subject, that there might be a useful application of a well known invention, of a paint which changes color on heating.

The merits and risks of automatic apparatus open a very wide question. Where springs are employed they should only be strained through a small part of their range, and carefully secured from all possible chances of getting heated, either by current passing through them, or by conduction or radiation from other sources. There should also be some provision for retaining the spring, or parts of it, should it happen to break. A single speck of rust on a steel spring will sometimes cause it to break, but the reliability of such springs as are used in watches and rifle locks may be urged in favor of their use when thoughtfully applied. Weights released by triggers and catches are frequently used with success, but the inertia may sometimes be a drawback. Special attention should be paid to hinges, etc., in such apparatus, since a slight defect may alter the adjustment or foul the whole mechanism. In switch work, it is quite common to have brass working on brass both of the same composition; this is sure to cut and bind in time. When it comes to talking of an automatic appliance that does not work, adjectives fail. Another point sometimes neglected is the provision of suitable buffers or arrangements for taking up the mechanical shock or jar. Unfortunately nearly all insulating materials are mechanically weak, so they should never be subjected to rough usage. In most cases these switches are set by hand and can therefore have strong reliable contacts. Where they have to be operated at a distance by means of a small current, the contacts are a serious trouble. An accumulation of small impulses can be used or the much abused mercury cups have to do duty. There are details in mercury cups however which make all the difference. The cups should be of iron, nickel-plated, the copper fork should also be nickel-plated and be shaped to cause as little splashing as possible.

For large currents and high voltages a multiplicity of breaks should be employed, so that a comparatively low speed will be sufficient. The author has had under his notice a switch for 15 amperes, 100 volts, in daily use for about three years. Three others, one for 15 amperes, 200 volts, the other two from 8 to 15 amperes, 100 volts, for 18 months. All these switches have given complete satisfaction and up to the present time have required absolutely no attention.

Switches requiring a shunt coil permanently in circuit are generally looked at askance, not for the sake of the coal here represented (though one does sometimes hear about the fuel consumed by a voltmeter), but mainly because the shunt coil has been known to break down.

If it were recognized that a coil will not stand unlimited cooking at say 150° F., that it is subjected to high pressure strains due to induction at times, and that in the case of alternating currents the wires must be specially supported and secured to resist the tendency to vibrate, then perhaps a coil could be made worthy of the occasion. What may be good enough for a single arc lamp is not good enough to bear the reputation of a central station.

So much for main switches. Plug connections have some point in common, though the problem is very much simpler. A taper plug between two blocks of metal, although almost universal for laboratory instruments, is rarely if ever used on a switchboard. A spring clip made to sandwich two projecting tongues is sometimes used, but the most usual form is a screw plug to connect bars on the back and front of a slate panel. Another form connects a back and front board by pushing a parallel plug through spring contacts. Ample weight of metal will in most cases make a sound connection since there is nothing to impair the original fit.

For very heavy currents, perhaps, in the case of screw plugs it may be well to have a spanner appliance instead of the ordinary fluted handle. The fire risks should also be considered in the event of a plug being taken out by accident while carrying a current. Facilities for replacing a portion of the bars damaged in this way would be advantageous.

Fuses, although so simple in conception, are often one of the most troublesome details. For low tension circuits certainly the problem seems elementary, yet there are cases where links of copper as large as the mains have been substituted for fusible metal.

There is a difference of opinion as to the most suitable metal for a fuse. Tin, lead and copper are generally employed. Then comes the question as to whether a thin strip, a single wire, a number of single wires stretched parallel to each other, or a number of small wires twisted together, makes the most reliable fuse.

The purity of the metal is also of great consequence. In designing a fuse the objects in view are:

1. Safety to attendants and adjacent instruments from molten metal or splintered insulating material.
2. A positive break in the circuit when the fuse does melt.
3. An accurate knowledge of the capacity under the condition of its mounting.
4. Durability.
5. A safe, simple and rapid means of replacing.
6. Mechanical strength, rendering it independent of skilled or specially careful handling.
7. Protection from other sources of heat, from imperfect contacts, etc.
8. Compactness.

Taking a few common examples they are mostly defective in one or two points.

The tin strip reduced in section at the center is generally suitable for low tension work, but it is almost invariably unprotected, and frequently in such a position that it will blow right in an attendant's face if he should happen to close a switch on a "short-circuit."

This type is the most durable and the most accurately gauged, but if a large range of sizes is required it is a nuisance to have to keep so many spares, especially as they are usually of a particular pattern. A rapid replacement is managed by throwing over a link or inserting a plug to connect another fuse already mounted. Otherwise it is satisfactory.

For high tension work, there are quite a lot of examples that will not break the circuit in case of a sudden "short circuit." Copper wire is generally most successful, since there is a less quantity of vaporized metal left in the path of the arc. In very small sizes, however, it is difficult to manipulate. Running in its normal condition at a high temperature it deteriorates rapidly. Again, with a variety of fittings and mountings, the value for any particular gauge alters considerably. Where the balance is held in favor of copper, there should always be an easy means of inspection at any time; either a transparent shield should be used, or a duplicate system employed, which will allow a fuse to be removed and examined without interrupting the supply. One well-known fuse consists of a length of wire soldered at either end to plugs having ebonite handles. The mechanical weakness of this arrangement may lead to serious accident. The operator gets one plug in, then perhaps breaks the wire and the live end sags down and touches his hand. Besides this, there is the inconvenience of having to solder the wire to the plugs. Another has a wire fitted into a gauge glass, sealed at the ends and half full of a liquid; these have been known to explode with great violence. Let us hope that they have long since joined the ranks of "our old type."

A lead wire incased in an india-rubber tube, or a copper wire in an asbestos sheath, has been used with success as far as the break goes; a wire in a glass or earthenware tube with the ends open is reliable if of sufficient length. One of the most recent designs has many novel features. The holder is in the form of a drawer made of earthenware, having a partition down the middle lengthwise. The fuse is a short length of wire, strained over the partition by means of two springs, the current being conveyed through flexible conductors, from two wedged contact pieces projecting from the back end of the drawer. When in use the drawer is filled with a special oil and pushed home, so that the wedges enter spring jaws. When the fuse wire melts the springs carry the ends down under the oil and so extinguish the arc. The makers claim that with

this fuse 500 amperes at 2,000 volts can be broken without any hitch.

The percentage of error in adjustment must be rather large, since it would take some time to warm up a large mass of earthenware and oil, and again, the unknown tension of the spring introduces another source of error. The fuses are arranged in duplicate for inspection and rapid replacement and are extremely compact.

(To be continued.)

THE PROTECTION OF STEAM HEATED SURFACES.*

BY C. L. NORTON,

Boston, Mass.

The investigation, of which this is a partial report, has been undertaken at the request of Mr. Edward Atkinson and has been pursued during a large part of the years 1896 and 1897, and is yet uncompleted. The first object sought for was the relative efficiency of several kinds of steam pipe covering now upon the market. The second object was to ascertain the fire risk attendant upon the use of certain methods and materials used for insulation of steam pipes. Third, an attempt was made to show the gain in economy attendant upon the increase of thickness of coverings, and to show also the exact financial return which may be expected from a given outlay for covering steam pipes. Further information is given on many minor matters and conditions affecting the transfer of heat from a steam pipe to the surrounding air.

METHOD.

The method adopted is one which, so far as I know, is original. A piece of steam pipe is heated from the inside electrically. The amount of electrical energy supplied is measured, and hence the amount of heat furnished is known. If the steam pipe is kept at a constant temperature by a given amount of heat it is because that amount is just equal to the heat it is losing, for if the supply were not equal to the loss the temperature would rise or fall. In other words, the heat put into the pipe is just equal to the heat lost from it by radiation, convection and conduction. By measuring the electrical energy supplied I can determine the heat put in, and hence the heat given out or lost. It must be borne in mind that a given amount of electrical energy always produces the same definite amount of heat, the amount of heat furnished by one electrical unit of energy being known with greater accuracy than the amount of heat given out by a pound of steam in condensing.

APPARATUS.

The apparatus for making tests by this method comprises several pieces of steam pipe of different diameters and lengths, heated electrically from within by means of coils of wire in oil. The oil is stirred vigorously and serves as a very efficient carrier of heat from the wires to the pipes. A brief description of the smallest tester may make the details of the apparatus more easily understood.

A piece of 4-inch steam pipe, 18 inches long, is closed at one end by a plate welded in, and at the other by a tightly fitting cover. This pipe is then filled with cylinder oil, and a coil of wire of sufficient carrying capacity and a stirrer are introduced into the oil. A thermometer is inserted in such a position as to record the temperature of the oil. An ammeter and voltmeter or a wattmeter may then be connected so as to record the amount of electrical energy supplied. The stirring must be brisk, and if enough power is put into the stirrer to be comparable with the electrical energy supplied, such amount must, of course, be added, as it also is converted into heat. It is my custom to suspend the apparatus in the middle of the room on non-conducting cords, and read the thermometer with a telescope, so that no heat from the person of the observer may be added to the supply given to the cover from within, and also that care may be taken not to produce air currents by walking near the apparatus during a test.

PROCEDURE.

In making a test the following operations are carried out, and observations are taken in the following order:

The current is turned on, and heat is generated in the wire coil until the wire, oil and steam pipe have reached the desired temperature at which it is proposed to test. The current is then gradually diminished until it is found to be of just the amount necessary to keep the pipe at this temperature without a rise or fall of $\frac{1}{10}$ of a degree in 30 minutes. A reading of the voltage and current is now taken at intervals of 30 seconds, and the watts and B. T. U. are computed from their average. We then have the number of B. T. U. lost from the outside of this particular pipe at this particular temperature. If now we place a steam pipe cover around the pipe, we shall find that a less amount of energy is sufficient to keep it at the required temperature, the difference being the amount of heat saved by the covering. The minimum length of time considered sufficient for the equalization of heat, or "soaking in" to the cover is six hours. If after a second heating of six hours no change in the conducting power is noted, the cover is considered in a permanent condition and is tested. Some covers, notably those composed wholly or in part of wool, cannot be considered dry and constant until after an exposure upon a pipe at 200 pounds pressure for six or eight days. Covers containing sulphate of lime are also slow in drying.

The three thermometers used were frequently standardized in naphthaline, and were examined to note any disagreement among themselves.

A discussion of the position of the tester and its exposure to air currents will be found in a later paragraph.

RESULTS.

A comparative test was made in 1895, upon a number of steam pipe covers on a 4-inch tester 16 inches long. The results obtained have been published in the circulars issued by the Boston Manufacturers' Mutual Fire Insurance Company and by the Steam Users' Association. The values were stated to be purely *relative*, the specimen being too small to give reliable data on the *absolute* conduction, and the surrounding conditions not being controlled other than to maintain them constant during the several runs. The ends of the specimen were covered by massive heads and the whole tester was situated within a few inches of a brick wall and a stone pier. It was called to my attention that the heat loss was probably high, and I agree that the exposure was such as to make it so, being a rather harsh test, but one which was rigidly uniform in its requirements of the several covers. In short, the actual loss of heat per square foot of the pipe surface was correct for that particular piece under the conditions of the test, but was not sufficient for the estimation of the actual saving which might be expected from the general use of coverings. I deemed it wise, therefore, to construct new heaters, four and ten inches in diameter and thirty-six inches long. These were suspended by non-conducting cords in the center of the laboratory, so as to hang freely and not be in contact with any conducting supports. Conduction up the lead wires and stirring rod was found to be negligible.

It seems to me that I have approached more nearly the conditions of actual practice than can be obtained by any other method of testing, except the actual use of a long run of pipe; and the determination of the amount of heat put into such a pipe by the "condensation" method offers many difficulties and is open to much uncertainty. I feel, therefore, that in adopting this method I am using a reasonable exposure for the pipe, and have an exceptionally good opportunity to measure the heat supplied.

Table I gives the relative conductivity of the various kinds of steam pipe cover tested up to April, 1898.

TABLE I.

Specimen.	Name.	B.T.U. loss per sq. ft. pipe surface per minute.	Ratio of loss to loss from bare pipe.	Thickness in inches.	Weight in ounces per ft. of length 4 in. diameter.
A	Nonpareil cork standard	2.20	15.9	1.00	27
B	Nonpareil cork octagonal	2.38	17.2	.80	16
C	Manville high pressure	2.38	17.2	1.25	54
D	Magnesia	2.45	17.7	1.12	35

F	W. B.	2.62	18.9	1.12	59
G	Asbestos air cell	2.77	20.0	1.12	35
H	Manville infusorial earth	2.80	20.2	1.50	...
I	Manville low pressure	2.87	20.7	1.25	..
J	Manville magnesia asbestos	2.88	20.8	1.50	65
K	Magnabestos	2.91	21.0	1.12	48
L	Molded sectional	3.00	21.7	1.12	41
M	Marsden infusorial earth	3.11	22.5	1.00	50
N	" " "	3.27	23.7	1.00	43
O	Asbestos fire board	3.33	24.1	1.12	85
P	Calcite	3.61	26.1	1.12	66
	Bare pipe	18.84	100.	..	..

It gives the results of the tests upon most of the samples tested, some being omitted when found to be of such low efficiency as to be of doubtful value.

Specimen A consists of granulated cork pressed in a mold at high temperature, and then submitted to a fire-proofing process.

Specimen B is similar in composition, but is made up of several strips of cork instead of two semi-cylindrical sections.

Specimen C is a sectional cover composed of an inner jacket of earthy material and an outer jacket of wool felt, the whole being one and one-quarter inches thick.

Specimen D is a molded sectional cover composed of about 90 per cent. carbonate of magnesia.

Specimen E is essentially an air cell cover, being composed of sheets of asbestos paper which have been indented before being laid up, the indentations serving to keep the thin sheets of paper from coming in close contact with one another, thereby causing a considerable amount of air to be held throughout the body of the cover.

Specimen F is composed of a wool felt with a lining of asbestos paper.

Specimen G is a cover made up of thin sheets of asbestos paper fluted or corrugated and stuck together with silicate of soda.

Specimen H is a plastic covering made of infusorial earth.

Specimen I is a low pressure covering similar to Specimen F.

Specimen J is a plastic cover, and called by the makers magnesia-asbestos. It contains only a slight amount of carbonate of magnesia.

* Paper presented at the Niagara Falls meeting (June, 1898,) of the American Society of Mechanical Engineers.

Specimen K—The magnabestos is a molded cover, containing about 45 per cent. of carbonate of magnesia and a considerable percentage of carbonate of lime.

Specimen L is composed mainly of sulphate of lime and some 20 per cent. of carbonate of magnesia, and has upon its outer surface a thick sheet of felt board.

Specimen M is a sectional molded cover. It is composed largely of infusorial earth from California.

Specimen N is similar to Specimen M, except that to its composition has been added some 45 per cent. of carbonate of magnesia.

Specimen O is similar to Specimen G, except that it has larger cells and contains much more silicate of soda. It is very hard and strong.

Specimen P is a sectional molded cover, composed mainly of sulphate of calcium. It has an outer layer of felt board.

In regard to the compositions of Specimens C, J, L and P, I desire to state that I have made no complete analysis, but I have satisfied myself that the principal ingredient is sulphate of calcium and *not* carbonate of magnesia. Prospective purchasers of pipe covers should not be misled by names. Since the appearance of Prof. Ordway's reports, it has been recognized that carbonate of magnesia was of great value as a non-conductor of heat, hence the name "Magnesia" has been applied to a great many covers. It is to be observed that there is no virtue in a name. Asbestos is merely an incombustible material in which air may be entrapped, but when not porous is a good conductor of heat. Magnesia is a most effective non-conductor. This name has been applied to many compounds of which the greater part consist of carbonate of lime, or plaster of Paris, materials which are not good as a heat retardent. The percentage of magnesia carbonate and plaster of Paris in several molded sectional covers is given in Table II.

TABLE II.

Specimen.	Percentage Composition.	
	$MgCO_3$.	$CaSO_4$.
D	80 to 90	3
C	less than 5	65 to 75
L	20 to 25	20 to 60
P	less than 5	75
J	10 to 15	none.

I have made no investigation of the effect of the raw materials upon the metal of the pipe, other than to satisfy myself that the cork, magnesia, air cell and Imperial covers cause no corrosion.

The conditions of testing were such as I have adopted as being reasonably near the conditions of actual practice. The room temperature was kept at 72 degrees Fahrenheit, and the openings into the room were carefully closed. It was found early in the series that variation in the amount of moisture present in the air altered the amount of heat lost from the covers, but no attempt was made to correct for this. The error introduced is not greater than one per cent.

It was found that the heat loss per square inch of the flat surfaces at the ends of the pipes was less by several per cent. than the loss from the sharply curved sides, and as all pipe covers tested were used to cover both sides and ends, the figures given in the table show a loss less than would be shown were the pipe surface wholly cylindrical, and more than if it were all flat.

The pipes were suspended from the ceiling, as described in an early paragraph, and the air circulating about them was due only to their own convection currents. The variation in thickness in different places on the same specimen was considerable, but an average of twenty measurements was taken and results given in the table to the nearest one-eighth of an inch. Owing to these variations in thickness, the results of a measurement of the efficiency of any one cover cannot be used to predict the efficiency of a second cover of the same make with an accuracy greater than two per cent. Two specimens of each make were tested, and in some cases four, the mean value being given in the table.

Table III gives the saving, in dollars, due to the use of the various covers.

TABLE III.

Specimen.	Name.	Loss B. T. U. 200 lbs.	Saving B. T. U.	Saving per year per 100 sq. ft.
A	Nonpareil cork standard	2.20	11.61	$37.80
B	Nonpareil cork octagonal	2.38	11.46	37.20
C	Manville sectional, H. P.	2.38	11.46	37.20
D	Magnesia	2.45	11.39	36.90
E	Imperial asbestos	2.49	11.35	36.80

P	Calcite	8.24	41.48	141.20	307.00
	Bare pipe	......	....	......	......

The money saving is computed on the following assumptions: Coal at $4 a ton evaporates ten pounds of water per pound of coal. The pipes are kept hot ten hours a day three hundred and ten days a year. If computations are made, as is sometimes done, on an assumption that the pipes are hot twenty-four hours a day three hundred and sixty-five days in a year, the saving is nearly three times that shown in Table III.

Generally speaking a cover saves heat enough to pay for itself in a little less than a year at 310 ten-hour days, and in about four months at 365 twenty-four-hour days.

It is evident that the decision as to the choice of cover must come from other considerations as well as from the conductivity.

The question of the ability of a pipe cover to withstand the action of heat for a prolonged period without being destroyed or rendered less efficient is of vital importance. The increasing use of cork as an insulator has led to many questions as to its ability to remain "fire-proof." I have exposed it to a temperature corresponding to 350 pounds of steam for three months, and to a temperature corresponding to 100 pounds for two years, and can detect no change, and I am satisfied, as well as one can be without the actual experience, that any suspicion of its ability to withstand continued heating is groundless.

The magnesia covering is, of course, unquestionable on this ground, being almost indestructible by heating.

The Imperial asbestos is also perfectly safe from any fire risks, as is the air-cell and fire board.

The Manville and Marsden infusorial earth and also the Manville asbestos-magnesia are liable to no accident from fire, nor is the Carey calcite.

It is to those covers, the "W. B." of the Watson Company, and the Manville sectional and others which possess a composite structure that I desire to call attention. I do not consider it safe to put upon a steam pipe wool, hair, felt or woolen felt in any form. The causes of risk are two: First, the wool may become charred by heat from the pipe and finally ignited. However, this can hardly happen, even on high pressure pipes, when the thickness of fire-proof material, asbestos, magnesia, or whatever it may be, is of as great a thickness as one inch. The second and most serious risk is from the presence in shops or mills of the long tubes of wool, dry as tinder, often connecting one room with another, and ready to flash at the slightest rise in the already too great temperature. I would even insist that the canvas jackets on the covers be fire-proof. An accident in my own laboratory has proved the actual danger of these wool felts, and I should not be willing to allow their use again. Their efficiency is high as non-conductors, but not higher than any other perfectly safe covers. If the wool is separated by about one inch of fire-proof material from the pipe it is not kept so hot and dry, and the risk from outside ignition is less, but I do not endorse the practice of many engineers in wrapping hair felt outside of a sectional cover. The saving due to this practice is indicated in Table V.

The following assumptions have been made in computing the Tables IV, V and VI: First, that all the covers cost $25 per 100 square feet applied. I realize this is a high figure, perhaps too high, yet it is not far from the list price of several makers, and any attempt to get a definite price from them revealed a maze of discounts and double discounts and flexible price lists too intricate for an uninitiated mind to unravel. In case the saving due to a cover which costs $20 instead of $25 is desired, the simple addition to the final saving of the $5 difference makes the necessary correction.

Secondly, by the advice of the makers, I have made an assumption that the cost is not nearly proportional to the thickness. As the thicker coverings are not now made in great quantities, the actual cost of their manufacture is uncertain.

Inspection of Table V shows the saving due to the use of hair felt outside a standard magnesia cover.

In five years 100 square feet of hair felt saves $7 more than its cost, and in ten years it saves $20 above its cost.

The further saving due to a second inch outside the first is $8 in ten years. Of course the well-known tendency of hair felt to deteriorate should be considered.

In the case of nonpareil cork, increasing the thickness from one to two inches raises the cost from

about $25 to $35 per 100 square feet, and increases the net saving in five years by $10 and by $30 in ten years. In other words, the second inch of material in use about pays for itself in two years, while the first pays for itself in about one year. The third inch does not increase the saving even in ten years. The second inch, therefore, more than pays for interest and depreciation, while the third fails to do this.

In the case of the asbestos fire board, a second inch in thickness causes a saving of $20 in ten years, the third and fourth inches showing a loss.

In general it may be said, therefore, that if five years is the length of life of a cover, one inch is the most economical thickness, while a cover which has a life of ten years may to advantage be made two inches thick.

In view of the custom which prevails to some extent of wrapping asbestos paper around a pipe, and surrounding the whole with hair felt, I made tests as to the temperature of the bounding line of the asbestos paper and hair felt, using a Le Chatilier thermo-electric pyrometer for this purpose. The different samples of asbestos paper give widely varying results, but a general idea of the protection offered by the paper may be had from Table VI.

TABLE VI.

Protection Afforded by Asbestos Paper.—Pipe at 200 Pounds Pressure.

Thickness of asbestos paper.	Temperature of pipe.	Temperature of inside of hair felt.	Pressure corresponding to the temperature of the inside of the hair felt.
1/64 inch.	384.7° Fahr.	356° Fahr.	146 pounds.
1/32 "	385.0° "	329° "	102 "
1/16 "	384.6° "	302° "	70 "
1/8 "	384.7° "	266° "	39 "

I have had my attention called to the varying loss from bare pipes when their surfaces were in varying conditions as regard rust, dirt, paint, etc. I therefore made a few brief tests to satisfy my mind as to the chance of there being any large variation which might influence my figure for the loss from bare pipe, viz., 13.84 B. T. U. per square foot per minute. The results are shown in Table VII.

TABLE VII.

Loss of Heat at 200 Pounds from Bare Pipe.

Condition of Specimen.	B. T. U. lost per sq. ft. per minute.
New Pipe	11.93
Fair condition	13 84
Rusty and black	14 20
Cleaned with caustic potash inside and out	13.85
Painted dull white	14 30
Painted glossy white	12 02
Cleaned with potash again	13.84
Coated with cylinder oil	13.90
Painted dull black	14.40
Painted glossy black	12 10

The rate of heat loss from a bare pipe is also affected by the air circulation and the temperature of the surrounding bodies. A few tests were made to indicate the magnitude of the errors likely to be caused by variation in these conditions, and a brief examination of some of the results may be interesting. They are given in Table VIII.

TABLE VIII.

Effect of Surroundings.

Condition and Position of Pipe.	B. T. U. lost per sq. ft. per minute at 200 pounds.
1. Standard condition hung in center of room	13 84
2. Near brick wall, between windows	11 26
3. Hung horizontally in center of room	12 06
4. Vertical 10 inch pipe — 36 inches long	13.18
4. Vertical 10 inch pipe — 18 inches long	11.42
5. Vertical, 18 inches long — 10 inches diameter	14.42
5. Vertical, 18 inches long — 4 inches diameter	15 20
6. 4 inches diameter in draft from electric fan	20.10

Table IX shows the varying loss from a bare pipe with the change in pressure:

TABLE IX.

Variation of Heat Loss with Pressure.

Pressure.	Bare pipe. Loss B. T. U. per sq. ft. per min.
340	15.97
200	13 84
100	8 92
80	8.04
60	7 00
40	5.74

A very thorough test was made of the common method of judging a pipe cover by the sensation of warmth given the hand on touching it, and nothing too harsh can be said of this practice. The sensation is dependent to such an extent upon the *nature of the surface* that it fails utterly to give any idea of the actual temperature. I have been unable to devise any method of so attaching a mercury thermometer to the outside of a steam-pipe cover as to make use of it as a testing device in measuring heat loss.

TABLE V.

Variations in Thickness, etc.

Specimen.	Saving in B.T.U. per sq. ft per minute.	Saving in dollars per 100 sq. ft. per year.	Net saving. 1 year.	2 years	5 years.	10 years	Approximate cost.
Magnesia:							
1⅜ inches thick	11.62	$37 75	$7.75	$15.50	$159	$317	$30
1⅜ inches thick and 1 inch of hair felt	12 38	40.22	5 22	15 44	166	367	35
1⅜ inches thick and 2 inches of hair felt	12 77	41.50	1.50	43 00	167	375	40

2 inches	11.48	37.25	2 25	39.50	151	337	35
3 inches	11 70	88.00	12 00	26.00	140	320	50
4 inches	11 83	38.40	26.60	11 80	127	319	65

I am desirous of calling attention to the advantages arising from the use of plastic rather than sectional covers. The ease of removal for repairs or alterations makes the sectional cover better for some work, but there is much pipe surface which might be covered securely with plastic where a sectional cover is soon ruined by vibration. Of course the plastic covers offer no possibility of leaky joints and long cracks. It should be borne in mind that in most cases about 20 per cent. of the entire surface to be covered is irregular, and must be covered by plastic or fittings. It will be well for prospective purchasers of pipe cover to see to it that their contracts call for fittings and plastic of as high an efficiency as the sectional cover shows.

I am now testing a considerable number of samples of non-conducting material, not perhaps classed as pipe covers, but used for heat insulation. Table X gives some figures concerning them which may be of interest.

TABLE X.

Miscellaneous Substances.

Specimen.	B. T. U. per sq. ft. per min. at 200 lbs.	Saving in one year per 100 sq. ft. pipe.
Box A.		
1 with sand	3.18	$31 60
2 with cork, powdered	1 75	39.40
3 with cork and infusorial earth	1.90	38.90
4 with sawdust	2 15	37.90
5 with charcoal	2 00	38.50
6 with ashes	2.46	36 90
Brick wall 4 inches thick	5.18	28.80
Pine wood 1 " "	3 56	33 80
Hair felt 1 " "	2.51	36 80
Cabot's seaweed quilt	2.78	35.90
Spruce 1 inch thick	3 10	33 90
" 2 " "	2 31	37 50
" 3 " "	2.02	38 50
Oak 1 inch thick	3.65	33.10
Hard pine 1 inch thick	8.72	32.90

The box A referred to in the table is a ¼ inch pine box, large enough to surround the pipe and leave a one-inch minimum space at its four sides. In it were tested several materials which I find are used in just this way for steam and cold storage insulation.

In concluding, I desire to express my thanks to those gentlemen who have assisted me in this test, and especially to Mr. John R. Freeman, Member of the Society, for his kindly advice.

LONDON NOTES.

[From our London Correspondent.]

The Waterloo & City Electric Railway Opened.

During several years past we have briefly recorded the progress made in the construction of the underground electric railways of London, particularly the line running from a point beneath the Waterloo Station, beneath the River Thames, under the very heart of the city of London at a great depth, to a central point near the Mansion House, where it is intended that several new electric underground lines shall converge. We have now at last to record the opening of the Waterloo line, which consists of twin tunnels constructed by the aid of the celebrated Greathead shield, the length of these tunnels being about 1½ miles. There are no intermediate stations.

The work was commenced about four years ago, various difficulties in the earth work at the Mansion House end, also other causes, having led to considerable delays. The Duke of Cambridge declared the line open on Monday, July 11, in the presence of a goodly company of officials, directors, engineers, etc., and the trains will be almost immediately available for public traffic. The line is owned and operated by the Waterloo & City Railway Company, but the London & Southwestern Railway, whose terminus is at Waterloo, is understood to be very closely connected with the undertaking. The electrical equipment has been carried out by Messrs. Siemens, Bros. & Co. The generating works are situated near Waterloo, the third-rail system is employed, and the American type motor cars are fitted with gearless motors. The track is of standard gauge (4 ft. 8½ in.) At one point the tunnels are laid beneath the great sewer and the tunnels of the Metropolitan Street Railway Company. The engineers for the line were Prof. A. B. W. Kennedy (Mr. Greathead it will be remembered died while the works were in progress), and Mr. H. Dalrymple Hay was resident engineer. The Waterloo & City is the second underground "electric" for London, the other being the well known City & South London, which is rapidly extending at both ends. As the Waterloo & City is a shorter and better district from a traffic point of view, it will probably show a more favorable return upon the capital outlay during the early years of running than did the City & South London. The Central London underground line is being pushed forward for completion as early as possible.

Discovery of a New Gas.

A special cable dispatch from Paris, July 19, to the N. Y. *Sun*, states that Prof. Nasini of Padua has communicated to the French Academy the result of his investigation of the gases issuing from the earth in volcanic districts. Among them he found coronium, which has hitherto only been known hypothetically as a constituent of the sun. His investigations suggest the probability of the presence of other new elements. Coronium seems to have a vapor density far smaller than hydrogen.

The General Electric Company owed, on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

UNDERGROUND FEEDERS FOR ELECTRIC TRACTION.*

BY CHARLES E. MORRIS.

In deciding upon the method to be adopted in laying underground feeders for electric traction, the relative advantages and disadvantages have to be weighed, presented on the one hand by a system of cables drawn into ducts, and on the other by cables buried in the ground and protected by armoring or bedded in bitumen.

The choice between the "drawing-in" and the "solid" systems is a problem which has occupied engineers of electric lighting schemes since the early days of the industry. Each system has its advocates; and judging from present practice, and the divided opinion which now exists, it appears that the question is still an open one. Of late years armored cables have been extensively adopted; but time has demonstrated that under some conditions, which hitherto have not been satisfactorily defined, the metal armoring corrodes to such an extent as to be no longer any protection to the cables. This may account for what appears to be a growing tendency among those who favor a "solid" system to abandon the use of metal sheathing and to lay the cables in troughs of wood, earthenware or iron, which are then filled with a bituminous compound. The diversity of opinion among lighting engineers as to the desirability of a "drawing-in" system appears to have had reference rather to distributing cables than to feeders; the reason being, no doubt, that the advantages of a duct are seriously interfered with when T-joints have been made on the cable within. Among those who use a "solid" system for distributing cables, there are a large proportion who fully recognize the value of a "drawing-in" system for feeders; and modern town-lighting schemes present numerous instances of the use of a conduit system for feeders, in combination with a "solid" system for distributors.

A "drawing-in" system possesses obvious advantages in the facilities it affords for withdrawing a faulty length of cable and replacing it by a new length, for increasing the section of copper to meet an augmented demand for current, and, by the provision of spare ducts, for drawing in extra cables as requirements arise. Where a "solid" system is used, either of these operations would necessitate opening and replacing the pavement at considerable cost, delay and inconvenience. Even if a built-in system be adopted for the cables necessary for the initial working of a scheme, it is manifestly advantageous to provide spare ducts to meet contingencies.

Assuming that, for traction feeders, a "drawing-in" system is desirable, there arises the question as to its cost as compared with protected cables buried in the ground. The kinds of duct in use in this country are practically limited to two; viz., cast iron pipes and earthenware conduits. Of late years, in connection with electric lighting, the use of iron pipes has diminished while that of earthenware has increased. In fact, earthenware conduits have been adopted for by far the larger portion of recently executed conduit systems. The cost of these ducts is considerably less than that of iron pipes. This is apparent when only a few ducts have to be provided; and, owing to the grouping of a number of ducts in one conduit, the cost per duct is reduced, and the disparity becomes even greater. The life of earthenware is practically unlimited. It is proof against the action of gas and other chemical agents present in the soil; and, being an inert substance, there is no risk of its exerting any deleterious influence on the cables within. What it lacks in strength compared with iron, for a given sectional area, is compensated for by increase in thickness. Owing to the smooth interior surface, cables may be drawn in with small risk of damage to the insulating material. Further, the conduits are easily and rapidly laid.

A modified procedure simplifies the jointing and effects a reduction in the cost. In forming the concrete bed, it is struck off at the level at which the conduit is to be laid. A wood template or mould is employed consisting of a board with battens fixed transversely on its under side at intervals corresponding with the lengths of the section of conduit. On removal of the template a continuous recess is left, in which the lengths of conduit are laid, their ends being closely butted together. Cement grout is then poured into the cavities formed by the cross-battens, which occur at each joint. The lower part of the joint is thus readily made perfectly sound, and a man can follow on and complete the upper part with cement in a mortar-like consistency. The whole is then covered with concrete. This method of laying has the advantage of being very rapidly executed.

For traction feeders the employment of concrete in the track construction affords an opportunity of installing earthenware conduits in a very satisfactory way. Buried in concrete they are effectually protected from damage which might otherwise be caused by workmen excavating or by settlement of the ground, and when so laid they form a sound constructional job, the depreciation of which may be regarded as nil. In joining the lengths of the conduit by the usual method the ends are bedded in Portland cement upon earthenware cradles, and the upper part of the joint is completed with cement laid on with a trowel.

* The *Railway World*, London.

Motor Gears.

The gearing of two motors, says the *Electrical Review*, London, by three bevel wheels, is an exceedingly useful adaptation of an old mechanical movement. This three-bevel wheel gear has many valuable properties, for it can be applied with a sliding clutch for reversing the rotation of a shaft, and is so used on lathes; it can be used for multiplying the speed of rotation, and as a differential gear it has been applied in Dr. Aron's electricity clock meter; it can also be employed on motor cars to enable one motor to drive two wheels at different speeds. The beauty of the gear applied to two electro-motors lies in the ease with which the motors may have their speeds varied or reversed. We should think it will be of great value in applying motors to many purposes besides steering-gear for ships.

The only drawback the gear has is that it is noisy at high speeds; but this could be overcome if the intermediate wheel can be made of raw-hide leather. The gear might be found useful on cranes and machine tools driven by electro-motors, where a wide range of differential speeds is necessary. For belt driving the intermediate bevels may be carried on the belt pulley, but for wheel and pinion drives it will be necessary to have a hollow shaft in one of the motors, through which the shaft carrying the intermediate wheel can pass to carry the pinion.

New Carbon for Arc Lamps.

Strauss, says an exchange, has patented, in Russia, a new kind of carbon for arc lamps. It is formed of 90 per cent. of very pure carbon and 10 per cent. of carburet of silicium reduced to very fine powder and agglomerated with pitch. Carburet of silicium contains no volatile element, it resists oxidation more than the other substances; but it is not a conductor, therefore it has to be combined with carbon. The inventor claims that he obtains in this manner a saving in current of 25 per cent., and a light of a richer tint and greater intensity than that of ordinary arc lamps. Its duration is 360 hours, and it is hoped that it will be increased to 1,000 hours. There are not as yet any official results to confirm these claims.

THE GENERAL ELECTRIC COMPANY.

We take the following from an article which appeared in the July 23d issue of the *United States Investor*, regarding the proposed reduction in General Electric Company's preferred stock, as being practically the same view of the situation that ELECTRICITY has all along taken. It says: "The management of the General Electric Company have issued a circular to stockholders accompanying the call for the special meeting to be held August 10, which is in some particulars a remarkable document. This circular is intended to explain why the management have decided that a 40 per cent. reduction should be made in the capital stock of the company.

"It will be remembered that the last annual report showed assets of 72 per cent. of the present entire capitalization, after charging off over $752,000, including $250,000 for the construction and equipment of a new foundry and a large and important machine shop. The report also showed that the company had earned enough to pay the regular dividend of 7 per cent. on the preferred stock, and a trifle over 3 per cent. on the common.

"In the face of this showing the preferred stockholders did not feel that they were warranted in consenting to a reduction in the capitalization of over 28 per cent., especially in view of the increasing earning capacity of the company. They felt that, even with this reduction, the company would be able with the large business ahead of it to pay 6 per cent. on the common stock, as well as 7 per cent. on the preferred, after the reduction, and they were naturally unwilling to scale down their equity to such a point as would allow common stockholders to receive the balance of the surplus earnings after 7 per cent. had been distributed on the preferred. If the whole stock was scaled down 40 per cent., it is felt that, with the business now on hand and in sight, the management would be able, after paying 7 per cent. on the preferred, to pay ultimately as high as 8 or 10 per cent. on the reduced common stock. The preferred stockholders did not feel, in short, that they were justified in making such a sacrifice for the benefit of common stockholders.

"ASSETS OVER-VALUED.

"But now the management have come out with a circular in which they show that the assets of the concern really do not amount to 72 per cent. of the present entire capitalization, and for the purpose of enabling them to carry their plan through, admit that they charged up their assets on a false valuation in their annual report, although they intimated then that the figures representing the patent account were nominal, and that the question of a revaluation of patents was one to which consideration would be given at the proper time. They stated at the same time, however, that the company had secured many important patents during the year by inventions of its engineers and experts, and by purchasing others, so that the implication was at any rate that there was to be only a moderate scaling down of the patent account, certainly not such a reduction as has been made.

"The management refer to this matter in the circular in the following language:

"'Appended is the consolidated balance sheet of the company of January 31, 1898 (being the close of the last fiscal year), as it appears in the last annual report of the company. Your directors, being of the opinion that the valuation at which patents, franchises and good will were carried in this balance sheet—namely, $8,000,000—was excessive, and that the fair and reasonable value of this item is the sum of $1,000,000, have, by resolution, directed this item to be reduced to that amount upon the books of the company as of June 30, 1898. Taking into account the estimated earnings of the company to August 10, 1898, your directors believe that a reduction of the share capital of the company as of August 10, 1898, to 60 per cent. of its present amount would make the share capital of the company substantially equal to the amount of the net assets which will then be on hand over and above the debts and liabilities

of the company. Any surplus net earnings from and after that date will then be applicable to the payment of accrued dividends on the preferred stock and future dividends on both classes of stock.'

"We are not inclined to doubt that $4,000,000 more correctly represents the actual value of its patents and franchises than $8,000,000, and that it would have been decidedly better for the company if that item had been put down at the former figure in January.

"ITS PATENTS AND FRANCHISES

were worth no more then than they are now, and the management undoubtedly knew then their actual worth as well as they do now. If they had been scaled down then, the management would now be relieved from the necessity of admitting that they had charged up their assets on a false valuation. The plan suggested some time ago by the management, it will be remembered, was to scale down their capitalization 50 per cent. Probably they thought when the annual statement was prepared that a concession of 10 per cent., that is, a scaling down of 40 per cent., instead of 50, might prove acceptable to the preferred stockholders. Events have shown that they were mistaken, if they thought so."

The American Street Railway Association Convention.

At the Convention of the American Street Railway Association to be held in Boston on September 6, 7, 8 and 9, a large and attractive display of electrical exhibits is expected and the following papers will be read:

"Maintenance and Equipment of Electric Cars for Street Railways." M. S. Hopkins, Electrician Columbus (O.) Street Railway Co.

"To What Extent Should Railway Companies Engage in the Amusement Business." W. S. Holmes, General Manager Metropolitan Street Railway Company, Kansas City, Mo.

"The Carrying of United States Mail Matter on Street Railways." W. S. Dimmock, General Superintendent Omaha & Council Bluffs Railway & Bridge Co., Council Bluffs, Ia.

"The Comparative Earnings and Economy of Operation Between Single and Double Truck Cars for City Use." Richard McCulloch, Electrical Engineer Cass Avenue & Citizens' Railway Co, St. Louis, Mo.

"Inspection and Testing of Motors and Car Equipments by Street Railway Companies." Frederick H. Perkins, Electrical Engineer Toledo Traction Co., Toledo, O.

"Cost of Electric Power for Street Railways at Switchboard; both Steam and Water." R. W. Conant, Electrical Engineer Boston Elevated Railway Company, Boston, Mass.

The General Committee is composed of the following gentlemen: C. S. Sergeant, 101 Milk street, Boston, chairman; E. C. Foster, Lynn; J. E. Rugg, Boston; C. S. Clark, Boston; A. A. Glasier, Boston; C. Q. Richmond, North Adams; John R. Graham, Boston; Robert S. Goff, Fall River; P. L. Saltonstall, Boston; E. P. Shaw, Boston, F. H. Dewey, Worcester.

Association of Edison Illuminating Companies.

This association will hold its Fourteenth Annual Convention at Sault Ste. Marie, Mich., on September 12–14 next. The *News* of that city says: "The association will come up on the last trip of the season of either the North West or North Land. Accommodations will be reserved at the Hotel Iroquois. It is expected that about 100 delegates will be in attendance. The selection of the Soo as the place of holding the convention this year is due to the well-directed efforts of Wm. Chandler, who extended the invitation to the association at its meeting last year at Niagara Falls. Mr. Chandler left no stone unturned to favorably present the advantages offered by his home city."

LEGAL NOTES.

On the 19th inst. at Pittsburg, Pa., an appeal was taken to the Supreme Court in the case of A. R. Todd against the Second Avenue Traction Company, operating the Pleasant Valley Railway, in which a verdict for $18,250 was rendered for the plaintiff for personal injuries received at the Sandusky street crossing in Allegheny. The only other case in Pennsylvania which compares with the Todd case is that of Herbert M. Frame versus the Electric Traction Company of Philadelphia, in which a verdict for $20,000 was rendered for the plaintiff, and the Supreme Court in an exhaustive opinion sustained the verdict.

The indictment for perjury found in October last against Leslie W. Ryan on the complaint of Henry Winthrop Gray has been dismissed by Judge McMahon in Part I, General Sessions, New York. Mr. Gray wrote to Judge McMahon, stating that he wished to withdraw the complaint. The charge against Mr. Ryan grew out of a foreclosure sale in 1894 of certain properties of the Thomson-Houston Electric Company of New York, of which Gray was receiver. In his letter to Judge McMahon Mr. Gray states that Mr. Ryan employed a stenographer in dictating his letter to him, and instead of the words "paid the receiver and for the benefit of creditors $70,000," the "and" was left out. Ryan had paid $7,000, but the remaining $63,000 had been placed to the credit of the reorganization committee of the Thomson-Houston Company.

In a suit brought in Philadelphia against the Philadelphia Traction Company to recover damages for the loss of a foot by a boy who was stealing a ride, Judge Pennypacker decided in favor of the railroad. The boy became frightened at the order of the conductor, who was in the car collecting fares, and fell off while the car was in motion, a wheel cutting off his foot. The plaintiff's counsel contended that it was the duty of the conductor to stop the car and see to it that the plaintiff was put down gently and in such a way that he could not hurt himself. Judge Pennypacker in his opinion says: "Is there such a duty? We know of no Pennsylvania case which has so held, and the principle does not commend itself to approval. To hold that such a duty exists, is in effect to say that the cars are run for the benefit of trespassers. To require the stopping of a car in order to put off intruders might be upon certain occasions a great embarrassment to both the company and its passengers. The true rule would seem to be that deduced from our cases, and upon which the most of them can be reconciled, that force, or that which is tantamount to it, cannot be used to the injury of child trespassers, but that the responsibility for care over them rests with their parents and guardians."

An interesting case was decided in New Orleans a few days ago by Judge Richardson, of the First City Court, which is reported as follows in the *Picayune*: "According to the petitioner's representation, T. S. McLoughlin, an electrician, wired a house for a resident on Palmer avenue, and the agreement was that the work would be done according to the rules of the underwriters' inspection bureau. When completed the bureau inspector examined the work and refused to issue the usual certificate, saying the rules of his bureau were not observed by the electrician. McLoughlin sued for a judgment to compel the bureau to issue the certificate, and asked for $20 damages for the refusal. The trial attracted much attention in underwriting and electrical circles. Amongst the witnesses were President Bemis of the Edison Company, Col. Nelson, the manager of the Tariff Association, and a host of electrical experts. McLoughlin claimed the work was safe and according to rule and that the bureau made it a practice to discriminate against him in its issuance of certificates. He introduced in evidence an award of Hon. Alfred Raymond, city electrician, in which, after an arbitration submitted by McLoughlin and the bureau, Raymond had adjudged the bureau guilty of favoritism and discrimination against McLoughlin in eighty-four cases submitted for arbitration. McLoughlin claimed that despite this arbitration Col. Nelson and his bureau persisted in their oppression and that the present case was only another instance of it. Judge Richardson found that the National Association of Underwriters had prescribed a printed code of rules for electrical work, but he concluded that by its own acts the local bureau, of which Col. Nelson is the manager, had practically abolished the National rules and set up rules of their own. Such being the fact, and there being no question of the safety of the work or the ability of the workman, Judge Richardson rendered judgment for the plaintiff, and against the bureau and Col. Nelson, and ordered that defendants pay the $20 damages claimed and issue to plaintiff the usual certificate provided for and necessary in the premises."

At Pittsburg, Pa., on the 18th inst., Judge Buffington handed down an opinion in the U. S. Circuit Court in the case of the Western Electric Company vs. Millheim Electric Telephone Company et al. The suit was for an alleged infringement of a patent for telephone circuit and apparatus known as the multiple system and now owned by the complainant. It was argued at the last term of court at Williamsport, Pa. The opinion is quite a long one and goes minutely into the technical details of the patent. The judge is of the opinion that the defences alleged have not been made good and that a decree should be prepared in favor of the complainant.

CANADIAN NOTES.

The first electric car traversed the streets of the city of St. Thomas, Ont., on the 15th inst. This electric street railway was begun on March 24 and has been completed and was opened for public travel on the 16th inst. The road is six miles long and it cost $80,000.

Hon. John Haggart, of Perth, Ont., and others have been incorporated under the name of "The Canadian Electric and Water Power Company," with a capital stock of $150,000, to produce and distribute electricity in Perth, as well as in other towns in the Dominion.

The works of the Ottawa Carbon & Porcelain Company are very busy at present. This is the only factory in Canada for the production of electrical porcelain and carbon goods. Ever since its establishment at the capital city it has made steady progress.

The Grand Falls Power Company of Grand Falls, N. B., in which Sir William Van Horne, Senator Proctor, Vermont, and Secretary of War Alger are largely interested, have secured additional properties at the falls necessary to carry on operations, and the announcement is now made that the work of harnessing the falls for saw and pulp mills, electric light and other purposes will begin at once. They expect to transmit electric power as far as Woodstock and River Du Loup.

The Carborundum Company of Niagara Falls has commenced the manufacture of its product in Canada under the patent which it holds. It has just erected a new factory building at Niagara Falls, Ont., but the electrical apparatus not having arrived in time for the plant to be utilized in accordance with patent provisions, in order to maintain its rights, the company, with considerable enterprise, erected a furnace in the power house of the Niagara Falls Park & River Railway Company, and there made the first carborundum produced in the Dominion.

A new electric power company has been formed in Ottawa. It will have a capital of $1,000,000. The promoter, Mr. Thos. Lindsay, says: "The company has practically unlimited water power at its disposal. Of course I cannot disclose the source of power at present, but we have 2,000 horse power to begin with and can easily obtain 5,000 more whenever we need it. We intend to supply Ottawa with electricity for light, heat and power. In addition to water power we will have a steam auxiliary."

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING PLANTS.

Brooklyn, N. Y.—New bids are invited for electrically lighting this borough. About two months ago, it will be remembered, at the opening of the bids then received it was found that the bid of the Kings County Electric Light Company was about 4 cents a lamp per night lower than that of its only competitor, the Edison Illuminating Company, and it was thought that the contract would be awarded to it at once, but the council committee having control of the matter held up the resolution that would have permitted Commissioner Kearny to award the contract, and the corporation counsel a few days ago made the discovery that the Kings County Company's bid was invalidated by the fact that the company could not fulfil the requirements of the specifications, not having sufficient facilities. Lately the two competing companies became amalgamated, and now new bids are called for, and in the absence of competition the citizens are looking forward with interest to the canvass of these bids.

Chicago.—Eighteen hundred gas lamps have disappeared from four or five of the city wards within the last two weeks and 300 new arc lights have been installed in their stead; these are operated from the new city light station at Rice and Lincoln streets. The new plant will furnish current for 1,000 arc lamps in the west and northwest portions of the city.

Duluth, Minn.—A resolution has been introduced in the council looking to the erection of an electric lighting plant of 3,500 arcs by the city. The cost is estimated at $89,000, and the resolution calls for a special election August 30 on the proposition to issue bonds to the amount of $100,000 for that purpose.

Duquesne, Pa.—The council and citizens of this town object to a recent increase in the cost of illumination by the McKeesport Electric Light & Power Company, and there is talk of the town erecting a plant in conjunction with the waterworks.

Gaylord, Minn.—The $5,000 electric light bonds having been sold, the village council will receive bids for erection of an electric light plant until August 2.

Houston, Tex.—The Citizens' Electric Light Company has begun the erection of a new building on the site of the old one destroyed recently by a boiler explosion. Blake Dupree, receiver for the company, says the new plant which it is proposed to construct will be up to date in every particular, an iron and brick fire-proof structure, supplied with all the modern electrical lighting appliances.

New Orleans.—An ordinance has been introduced in council which proposes that a contract for electric lighting be given to a company which has made an offer to furnish the city with light for a certain number of years on a novel plan. The contractor is to operate the plant at his sole cost, including the cost of repairs, etc., and insurance for the number of years to be stated in his bid. He is to receive from the city, beginning at the close of the present contract in 1902, the sum of $210,000 annually, payable monthly, the contractor agreeing to take his pay for the construction of said plant out of the profits made by him during this period. At the end of this period the contractor will deliver the plant to the city in good order, and without any further payments from the city. No light shall be furnished to any person or corporation except the city.

Ocala, Fla.—The General Electric Lighting Company has accepted the council's offer of $8,000 in city bonds for its lighting plant. The transfer will take place August 1.

Portland, Ind.—The city's electric light plant was damaged to the extent of about $5,000 by a fire in the building in which it was located on the 14th inst.

Tonawanda, N. Y.—The lighting contract has been awarded to the Tonawanda Light & Power Company on the same terms as existed last year.

Worcester, Mass.—The county commissioners and architects recommend the installation of an independent electric lighting plant for the new county buildings, and it is probable that such a plant will be put in.

STREET RAILWAYS.

Asbury Park, N. J.—Undisputed right of way from Como to Pleasure Bay has been obtained by the Atlantic Coast Railway. The suit of Hutchinson and others against the mayor and council of Belmar, to set aside the franchise recently granted to the Atlantic Coast Electric Railway Company, has been decided in favor of the borough of Belmar, and the franchise was therefore determined to be legal.

Brooklyn, N. Y.—The new Rockaway Beach line of the Brooklyn Elevated Railroad Company has been in operation for several days and is well patronized. The cars start from the New York end of the big bridge.

Chattanooga, Tenn.—The large motors for the Patton motor car of the Chattanooga Rapid Transit Company have arrived and will be set up in the cars in a few days. The officials of the road are confident that the Patton system will fulfil all expectations with the increased power secured by the addition of the large motors. All the suburban lines, it is understood, will be equipped with this system.

Clinton, N. Y.—The New Hartford & Clayville Electric Railway Company is said to have secured the right of way from New Hartford to Clayville, and just as soon as the same can be secured to Clinton the company will be incorporated and begin the work of building the lines. The company, it is stated, will have no lack of capital, and will ask nothing of either village save the right of way. Ex-Supervisor Seaton of New Hartford and C. L. Fitchard of Utica are actively engaged in the preliminary work.

Dayton, O.—The Board of City Affairs has granted a franchise to the Dayton & Western Traction Company, which will operate its cars over the Third and Fifth street lines of the City Railway Company, building a section of track on College street to connect the Third and Fifth street tracks.

Edgartown, Mass.—Interest is being revived in the proposed electric road between this town and Cottage City, and it is thought subscriptions enough can be secured here to insure the building of the line.

Elyria, O.—"The value of an electric railway to abutting property," the "Republican" says, "is beginning to be appreciated. Not long ago a seventy-two acre farm, a short distance this side of Ridgeville, sold for $15,000 to a Cleveland party. Five years ago $10,000 would have been regarded a good price for this property. Owners of property between Elyria and Amherst could safely mark up their lands twenty-five per cent. along the line of an electric railway should one be constructed between the two places."

Grafton, Mass.—The selectmen have granted a franchise to the Grafton, Upton and Milford Street Railway Company to build an electric street railway from the Grafton-Upton boundary line to Farnumsville by way of Grafton Center.

Hartford, Conn.—The third-rail line between this city and Bristol is now in operation. All the steam trains which have run the short trips between this city and Bristol have been discontinued.

Milwaukee, Wis.—Speaking of the Fox River Valley Electric Railway, Henry C. Payne, president of the road, says the line will be extended south to Oshkosh, and north to Kaukauna this year. He says the part of the line now in operation is proving a very satisfactory piece of property. At the annual meeting of the company held at Appleton recently all of the old officers were re-elected.

Nelson, B. C.—C. S. Drummond, who represents the British Electric Traction Company of London, has made application to the city authorities for a 30-year franchise for an electric street railway. If built, this road will be the first of its kind in the Kootenays.

Olympia, Wash.—The car barn of the Olympia Light & Power Company was burned on the 13th inst. Several cars were ruined and the loss to the company is about $15,000, partially covered by insurance.

Penn Yan, N. Y.—A company has been organized, with George F. Andrews, of Oswego, as president, to finish and equip the road from Savona to Keuka, and efforts are being made to secure a connecting line between Keuka and Penn Yan.

Pittsburg, Pa.—The "Dispatch" of the 17th inst. says: "Allegheny county's newest electric railway, the Monongahela line, which is to speedily transport passengers to and from Pittsburg, Braddock and Duquesne, will be in perfect operation shortly after September 1. Wilkins & Davison, the engineers in charge, made this announcement yesterday. The road will be double track along its entire course and the cars will spin along on 90 pound steel girder rails. The cost of the work now being done will probably aggregate $300,000, and the route over which the cars will run has presented more difficult engineering problems than were encountered in the building of any line in the county. The Monongahela Street Railway Company is composed of the Homestead and Highland line and the Homestead and Braddock Traction Company."

Sandusky, O.—The sale of the Sandusky Street Railway has been confirmed by the court and the new owners are in control.

St. Clair, Mich.—The city council has accepted $1,000 in lieu of all claims of the city against John B. Dyar for his failure to put through his projected electric road. Mr. Dyar gave the city a bond for $2,000, but was unable to fulfil his engagements owing to financial obstacles.

St. Louis.—The annual return of the street railways of St. Louis, giving the total number of trips made by cars and the number of passengers carried during the year ending July 1, has been filed with the City Register. The total number of trips on all lines was 1,355,988 and the total passengers carried was 30,013,201. The heaviest showings were made by the Lindell and the Missouri.—Arrangements have been completed for a new electric railway in St. Louis County, from Bobringville, the headquarters of numerous sharpshooters' societies, to a connection with the Southern Electric Railway at Carondelet.

Toledo, O.—The Chamber of Commerce has passed resolutions indorsing the project of building an electric railway from Toledo to Lyons, Mich., a distance of 36 miles, and also agreed to pay Dr. John Smith of Pontiac, Mich., the chief promoter of the road, a cash bonus of $5,000, the amount asked, when the road is completed and in operation.

Washington, D. C.—A certificate of the change of name of the Eckington & Soldiers' Home Railway Company of the District of Columbia to the City & Suburban Railway of Washington has been filed with the Recorder of Deeds.

Watertown, N. Y.—The annual meeting of the Black River Traction Company was held here recently. The officers chosen early in January, when the new company came into existence, held over by tacit understanding. These officers are J. A. Lebkuecher, Newark, N. J., president; H. F. Inglehart, vice-president; George H. Walker, secretary, and B. B. Taggart, treasurer. The reports showed that since the company took charge of the road it has gained business and is now nearer a paying basis.

Worcester, Mass.—A movement is on foot for the consolidation of the Worcester & Marlboro and the Marlboro, Framingham & Southboro Electric Street Railway Companies, and if it is consummated it will mean a ride in the electric cars from West Warren to Boston, through Worcester, Framingham, Natick, Wellesley and the Newtons, a distance of about 80 miles. The Marlboro, Framingham & Southboro line is in process of construction.

MANUFACTURING, ETC.

Cleveland, O.—The Walker Manufacturing Company of this city has, it is said, just received one of the largest single orders ever booked by that firm. The order came from Paris and was for equipment for 500 electric street cars. This includes 1,000 motors, 1,000 controllers, 500 trolleys and other details. The order will amount in value to over $500,000.

Fort Wayne, Ind.—The largest flag in the State was unfurled at the works of the Fort Wayne Electric Corporation on the evening of the 16th inst. The flag is 54 feet 6 inches long and 32 feet 6 inches wide; the stripes are each 2 feet 6 inches wide, while the total weight of bunting used in its construction is sixty pounds. The pole from which the flag is to wave is 150 feet long and is surmounted by a golden eagle of large dimensions. Mr. E. A. Barnes, acting superintendent of the works, in presenting the flag to Mr. Wood, the electrician and general superintendent of the company, said: "Mr. Wood: At the request and on behalf of our faithful employees, I have the honor and great pleasure of presenting to you for Mr. McDonald this beautiful flag and eagle. It is offered not alone as a token of their high esteem for Mr. McDonald and their appreciation of his untiring efforts in their behalf in perpetuating these works and keeping it in this city, where it stands as a creditable monument to its promoters, but also as a testimonial of their loyalty to our glorious country and its cause." Mr. Wood made a pleasing speech in response and read telegrams from Mr. McDonald regretting his unavoidable absence. The flag was then hoisted by the men, while a great cheer rose from the 12,000 spectators who had assembled to witness the ceremony, and the band played the "Star spangled Banner." Some suitable remarks from Mr. Worden followed and then Judge Taylor delivered an eloquent and patriotic address.

TRANSMISSION PLANTS.

Baltimore, Md.—The firm of J. G. White & Co. of this city has been awarded the contract to put in place the equipment necessary to conduct an electric current into Canada from the big power station at Niagara Falls.

Columbus, Ga.—The Columbus Power Company has signed contracts for the erection of one of the largest and finest electric plants in the world, developing 10,000 horse power by water. President H. M. Comer of the Central Railroad of Georgia is head of the company.

Jamaica.—C. O. Palmer, manager of the Sun Life Insurance Company at Kingston, Jamaica, speaks highly of the project of harnessing the Rio Cobre by the West Indian Electric Company, which is one of the largest schemes ever ventured in Jamaica. The works, which have made considerable progress, are situated near the great tunnel at Boy Walk, at which point the river is 160 feet wide. The dam will stretch from one bank to the other, to be imbedded in the solid rock. In order to provide against all contingencies, the dam will be three times as strong as its estimated pressure. The foundations of the dam have already been built. The concrete and masonry sunk in the rock of the river bottom will go ten feet below the water, and above the water the walls of the dam will rise some nine feet. The water is taken in from the dam by a pipe eight feet in diameter. The pipe will convey about 20,000 cubic feet of water, or about 120,000 gallons a minute to the power works. It is provided with a steel valve to regulate and control the supply of water, and runs alongside the river for a mile and a quarter from the dam to the power house. The power house will be built entirely of steel and concrete, the steel work alone weighing 250,000 pounds. The river in its course for a mile and a quarter drops about 47 feet, which, added to the foot of the dam, amounts to 56 feet, which will be the fall of the pipe in its course to the works.

Sanford, Me.—The Sanford Mills Company are erecting a stone dam at the old falls of the Mousam River. The dam is 450 feet long and in places 32 feet deep. Its entire length rests on a solid ledge foundation, thus eliminating all danger of another washout like that which carried away a section of the left wing early in the spring. It is expected that the work of construction will be completed September 1. Work on the power station was begun last week. When completed, 2,500 horse power will be generated, part of which will be transmitted to the Sanford mills, eight miles distant, and part utilized for the Sanford & Cape Porpoise Railroad.

COMPANY MATTERS.

Boston, Mass.—The Railroad Commissioners have authorized the Mystic Valley Street Railway Company to buy the Arlington & Winchester. The Mystic Valley was authorized to issue $50,000 of stock. The roads in question will exchange stock, share for share. The commissioners have also approved an issue of $80,000 bonds, 5 per cent., by the Norton & Taunton Railway Company. The issue will be used for construction purposes.

Kalamazoo, Mich.—W. A. Foote has purchased a three-fourths interest in the Kalamazoo Electric Company from J. K. Wagner, Bush & Tate, and B. A. Bush. The capital stock is $100,000. The plant will be increased and the service improved. The officers are: President. W. A. Foote, Jackson; secretary, S. S. Hulburt, Battle Creek; treasurer, James B. Foote, Jackson. W. A. Foote is now interested in the Battle Creek, Jackson and Albion electric lighting plants.

Newark, N. J.—The People's Light & Power Company of Newark probably holds the record as an absorptive corporation. It now controls and has absorbed the following companies: Newark Electric Light & Power Company, Newark Schuyler Electric Light Company, Thomson-Houston Electric Company, Central Power Company, Consumers' Electric Light & Power Company, Excelsior Electric Company of Harrison, Kearny Electric Light & Power Company, Jersey City Electric Light Company, Hudson County Electric Company, Essex County Electric Company, Suburban Electric Light & Power Company, Montclair Light & Power Company, Edison Electric Light & Power Company, People's Gas Company.

Rockford, Ill.—C. F. Warner, receiver of the Rockford Electric Power Company, has published a notice requesting all persons having claims or demands against the company to present the same to him within sixty days from July 13.

MINES.

Colorado Springs, Col.—The Colorado Electric Power Company's plant is nearing completion. The electric hoists the company installed at the Cripple Creek mines are handsome pieces of machinery, are very compact, will not take one-third of the space required by a steam hoist and can be successfully operated by any steam engineer who knows his business. Aside from the very material saving which will be made by using electric power at the mines, there are many other advantages, for there is no longer any need for the use of coal with all its trouble and dirt. There are no pipes to burst in winter, no boiler repairs, the hoister requires oiling only once a month, and there are many other conveniences which will readily be thought of, which are attendant upon the use of electricity instead of steam for power purposes. The hoists are now being placed on different properties in the camp, and at the rate that orders are now coming in for them it is quite evident that it will be but a very short time before the entire power output of the company will be sold. The electricity will be adapted so that it can be used for hoisting, for running air compressors and pumps, for lighting purposes and for the numerous other things for which power is used in the mines of the camp.

Empire, Col.—A. R. Specht is putting in a plant here to generate electricity to be furnished to mine operators in this vicinity.

Tuscarora, Nev.—The Dexter Company contemplate the establishment of an auxiliary electric plant at their gold and cyanide works to furnish some 300 additional horse power.

ELECTRICIANS IN THE WAR.

Albany, N. Y.—Lieutenant Henry G. Opdyke, United States Volunteer Signal Corps, who has been recruiting volunteers for the corps, has left for Washington with many electricians and telegraphers from Albany. With them have been placed volunteers from other places, the telegraphers numbering more than the others. The men will be at once enlisted into active service and it is supposed will be sent to Manila.

Topeka, Kan.—Frank W. Smith has received a letter from his brother William, who is electrician on the United States gunboat Resolute. The letter is dated Guantanamo Bay, July 6. He witnessed the naval battle which ended in the destruction of Admiral Cervera's squadron and gives a graphic description of the running fight. After the Spanish ships had been driven ashore and the work of rescue began, he says: "The boats brought us over 500 scared looking greasers, who thought we were going to cut their throats and hang them as soon as we got ashore, but they soon found they were in the hands of civilized people who had no intention of harming them. I was surprised when they were brought alongside. Instead of a lot of dirty looking, starved looking villains, they were all dressed in clean white, better than our own men, and each had a bag and outfit in many respects more complete than our own. They all wore clean white pancake hats and looked pretty decent. Some had their pockets stuffed with eatables, canned fruit, cookies, etc., which tended to disprove the statements that they were being starved and led us to believe that they had fared better than we had. But the fact is they had looted their ship when they saw they would have to give her up. No doubt their officers had fared well enough. On the deck of the Cristobal Colon were cows and chickens and the officers had evidently been having fresh milk."

PERSONAL AND MISCELLANEA.

E. F. Hebard, formerly general manager of the Consolidated Traction Company of New Jersey at Newark, has been elected general manager of the Cincinnati & Miami Valley Traction Company in place of W. G. Wagenhois resigned.

The Rockland, Mass., "Independent" says: "H. H. Hallett, who is a born inventor, is devoting his attention to the third rail electric system. The danger to life prevents its use in thickly settled localities, except with the overhead wire. Mr. Hallett is experimenting with a device which will leave the rails uncharged with electricity as soon as the car passes over them. He is confident that he is on the right track and will continue experimenting until his idea is perfected."

Charles Huff, employed by the Citizens' Company at Indianapolis, was killed instantly on the 16th inst. while repairing overhead wires. While standing on a ladder that rested against one of the iron cross-arms of a pole, and in disobedience of the instructions of the foreman and other men on the ground, he grasped the iron arm with one hand and the live wire with the other, forming a short circuit. Huff fell to the tracks senseless, and before his companions could raise him he was dead. He had only been working in the city a short time.

A centipede about eight inches long was found in a coal bin at the Plymouth (Mass.) Electric Light Company's station the other day. One of the men reached down into a cavity in the coal for some purpose and the insect clutched his arm, but was knocked off instantly. Probably being in a cool place made the creature sluggish, and it was unable to inflict the terrible injury that it is capable of. It is probable that the last cargo of coal landed there came in a vessel which had been in some West Indian port, and there the Spanish guerrilla stowed himself away in the hope of nabbing some Yankee.

The Belleville, Ill., "Democrat" states that Michael McKaveny, a motorman on the East St. Louis Electric Railway, resigned his position a few days ago and left for Ireland where, it is claimed, he will receive an inheritance of £20,000 or $100,000. He received a letter from an attorney in Ireland, who informed him that he was a collateral heir of an uncle who died recently. The old man was worth about $200,000, which amount will be divided between McKaveny and his brother.

W. B. Viall has resigned his position with the Stanley Company at Pittsfield, Mass., and has taken an interest in the Eureka Electric Company, buying the share formerly owned by the late Michael Leavey. Arthur Wentworth takes Mr. Viall's place with the Stanley Company.

As a matter of economy the management of the Vincennes, Ind., street railway company advertised last week for women to act as conductors. More than fifty applications were made, and five young women were selected out of the lot. The salary will be only about $5 a week, or $20 per month. The uniform consists of a black suit of much the same pattern as that worn by girls in bicycling. All will wear caps inscribed "Conductor." The girls have made several trial trips, and have been placed on regular service.

A prophecy has been made that it will not be long before there is a belt of smiling gardens and fields crested with palms and inhabited by a contented people on both sides of the ancient river Nile, all the way from Cairo to Khartoum. A scheme is already well under way for tapping the river at the higher level above the cataracts, conducting the water to vertical shafts, down which it will fall to drive turbines, and using the power so generated to run dynamos, from which electricity in the form of alternating or continuous current will be transmitted to points near or remote. The water after passing through the turbines will be restored to the river at a lower level, or else used for irrigating the land. There will be no waste of material, as in burning coal, and no smoke to pollute the limpid air of the desert. Electricity will be applied not only in pumping for the irrigation, but in driving the machinery for preparing the raw products of the soil, spinning cotton, weaving silk and many other industries.

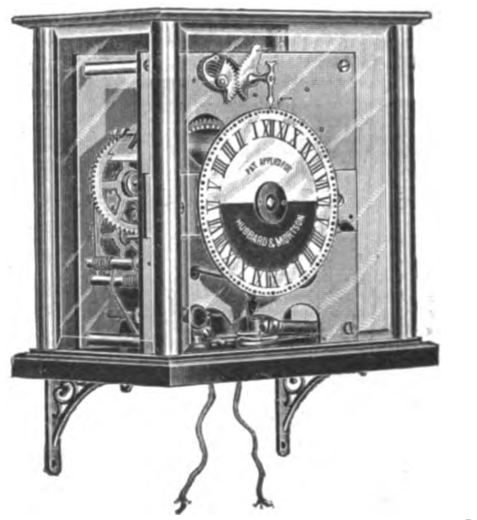
George Bock, engineer at the East End plant of the Allegheny County Electric Light Company, Pittsburg, Pa., was killed by electricity at the company's station on the 14th inst. A high potential current of 5,500 volts from the down town power house is divided in the East End plant, and Bock was about to turn 2,400 volts of this current into wires running to Homewood. Bock was a short man and the switchboard on which the change was to be made was barely within his reach. Two plugs, with insulated handles had to be removed from the top of the board and inserted into holes farther down, and when the man reached these plugs he grasped the bare metal instead of the hard-rubber handles. He succeeded in removing the plugs without sustaining any injury, but when they were placed in the lower holes the entire current of 2,400 volts was passed through Bock's body. As soon as Bock sustained the electric shock he fell forward against the switchboard, not releasing his hold of the brass plugs, however. In this position he was found by his fellow-workmen, who laid him on the floor and immediately made every effort to revive him. Dr. P. J. Eaton of North Highland avenue was summoned and in the meantime the workmen attempted to renew respiration, as is done in cases of drowning. When the physician arrived no signs of life were apparent. The unfortunate man was only 23 years old and unmarried. He had been in the employ of the company 12 or 13 years.

COMMERCIAL PARAGRAPHS.

An Automatic Time Switch.

From time to time several cumbersome and more or less clumsy appliances for automatically turning off electric currents have been put upon the market. These have accomplished the one purpose of turning off the switch, and a simple alarm clock movement has usually released a gravity contrivance whereby the cut-out is accomplished. The Automatic Time Switch Clock, illustrated herewith is the first appliance that has ever accomplished the two-fold movement of turning on and off the electric switch at any time of the day or night at which the clock may be set. This is without doubt one of the most important mechanical appliances for controlling electric circuits and will be of interest to practical electricians, engineers and every householder.

As may be seen from the illustration, the Automatic



Time Switch Clock presents a handsome appearance. It looks like an elegant French clock, with its polished movements, brass corner pillars and panels of plate glass enclosing the clock movement and switch train. The case is mounted upon a substantial base of slate upon which is placed an ordinary four-pole electric switch. The wires to be controlled are cut into this switch in the ordinary manner.

The operation of the time switch is exceedingly simple but most practical and thoroughly effective. A twenty-four hour dial, which makes one revolution every day, revolves under a fixed pointer at the top. At the back of this dial are supplied two movable pointers held in position with sufficient friction by a spring disk. These pointers may be set at any time of the day or night and are fixed rigidly in position when set by pins which engage in a row of holes parallel with the circumference of the disk. When the first pointer reaches the reading point at the top the other end trips an alarm wire which connects with the time hook and sets in motion the train which turns the switch. As time passes the second pointer approaches the point of reading, reaches it and sets the train in motion again, accomplishing the second motion of the switch and turning off the lights. Absolutely all the attention that this requires, after having been set for the hours desired, is winding once a week.

The switch arranged on a slate base meets all the requirements of the Board of Underwriters in the different States as well as the National Board of Underwriters. The Hubbard & Mortson factory, where the new time switch is made, is located at 42 Union Place, Hartford, Conn.

The Electric Appliance Company of Chicago are very proud of the fact that they will soon complete the seventh year of their Electrical Supply business. The Electric Appliance Company claim, and we believe justly, that after confining themselves strictly to the Electrical Supply business as they have for this period of time, they should be in the best possible position to handle that branch of the electrical business successfully. It is very apparent from the volume of business they are now doing and their position in the electrical field that their business has been thus far very successfully handled.

INCORPORATIONS.

The Tuxedo & Embla Park Water & Electric Light Company, Baltimore, Md.—to supply Embla Park and Tuxedo with water and ultimately with electric lights. Capital stock, $25,000. Incorporators: Granville S. Wilson, Henry A. Leonard, John H. Neudecker, Frederick E. Wilson and William F. Smith.

The Hadaway Electric Heating & Engineering Company, New York City. Capital stock, $50,000. Incorporators: Harold S. Mackaye, Harcourt Brigham and Nelson Hiss, all of New York.

The Fairfield Traction Company, Lancaster, O.—to build an electric road in the suburbs of Lancaster. Capital

stock, $100,000. Incorporators: Henry B. Peters, William Davidson, George P. Rising, L. N. Ingham and Frank C. Week.

The Chicago & Fox Lake Electric Railroad Company, Rockefeller, Ill.—to build an electric road from a point in Lake County, Ill., on the east line through McHenry County to west Wisconsin State line. Capital stock, $20,000. Directors and incorporators: John W. Green, Charles E. Soule, Jr., William A. Kawson, Stewart Spaulding, Frank N. Hillis, F. W. Pringle.

The Kinderhook Power & Light Company of Rensselaer County, N. Y.—to furnish electricity for heating and lighting purposes in the cities and villages of Rensselaer County. Capital stock, $50,000. Directors: James Purcell, of Valatie; James R. Hughes, James Hogan and John Ritz, of Stuyvesant Falls, and William D. Barnes, of Brainerd, N. Y.

The Electric Amusement Company, Baltimore, Md. Capital stock, $10,000. Incorporators: John Fay Palmer, of Cleveland, O.; George F. Lurssen, Otto M. Mattfeldt, Arthur L. Herring and Herman H. Lurssen, all of Baltimore.

The Clear Creek Power Company, Denver, Col.—to acquire, hold and develop water rights and generate electric power and sell it in Clear Creek and Gilpin counties, Col. Capital stock, $1,000,000. Incorporators: A. R. Sprecht, Dumont, Col.; F. Rockerfeller, M. A. Bradley, M. Henderson, D. R. Taylor, H. P. Malone and E. G. Tilotson, all of Cuyahoga County, Ohio.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JULY 19, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

607,610. Electric-Railway System. Sidney H. Short, Cleveland, O. Filed May 24, 1897.

607,611. Electric-Railway System. Sidney H. Short, Cleveland, O. Filed July 9, 1897.

607,6 2. Trolley-Base. Harrison G. Taylor, Montreal, Canada. Filed Sept. 27, 1897.

607,697. Electric Railroad. Clarence A. Myers, Atlantic City, N. J. Filed Nov. 18, 1897.

607,414. Car-Fender. James H. Lewis and Joseph M. Courtney, Kansas City, Mo. Filed July 19, 1897.

607,514. Car-Fender. Andrew J. Lawton and David L. Macaffree, Colorado Springs, Col; said Macaffree assignor to said Lawton. Filed March 14, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

607,589. Electric-Arc Lamp. John H. J. Haines, New York City, assignor to the Haines Electric Company, Jersey City, N. J. Filed Oct. 29, 1896. Renewed May 12, 1898.

ELECTRICAL MACHINERY AND APPARATUS.

607,451. Electromagnetic Motor. Archie B. McMillan, New York City. Filed July 7, 1897.

607,469. Box-Filling Machine. Francis H. Richards, Hartford, Conn. Filed Oct. 19, 1897.

607,473. Recording Apparatus for Weighing-Machines. Francis H. Richards, Hartford, Conn. Filed April 16, 1897.

607,475. Weighing-Machine. Francis H Richards, Hartford, Conn. Filed Sept. 25, 1897.

607,510. Electrical Resistance. Harvey S. Chase, Boston, Mass., assignor, by mesne assignments, to the American Electric Heating Corporation, same place. Filed Jan. 11, 1897.

607,551. Electric Regulator. Joseph A. Powers, Lansingburgh, N. Y. Filed Oct. 28, 1897. Renewed June 17, 1898.

607,593. Dynamo-Electric Machine. William B. Sayers, Glasgow, Scotland, assignor to himself and Mavor & Coulson, Limited, same place. Filed Dec. 21, 1897.

607,608. Rheostat Michael J. Shiels, Westfield, N. J. Filed Jan. 7, 1898.

607,6 9. Field-Magnet for Electric Machines. Sidney H. Short, Cleveland, O. Filed May 4, 1896.

607,617. Regulating-Switch for Electric Circuits Harry P. Davis, Pittsburg, and Gilbert Wright, Wilkinsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed Sept. 18, 1897.

607,621. System of Electrical Distribution. Benjamin G. Lamme, Pittsburg, Pa. Original application filed Jan. 28 1897. Divided and this application filed Dec. 16, 1897.

607,638. Electric-Line Switch. Antoine B. Du Pont. Detroit, Mich., assignor to the Steel Motor Company, Johnstown, Pa. Filed Aug. 12, 1897.

607 672. Controller. Thorsten von Zweigbergk, Cleveland, O., assignor to the Walker Company, same place. Filed April 8, 1898.

607,737. Dynamo Electric Machine. Adolf G. Eigner, St. Petersburg, Russia, assignor to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed May 7, 1898.

607,764. Circuit Arrangement for Electrical Apparatus. Julius Meisler, Vienna, Austria-Hungary, assignor to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed Dec. 13, 1897.

TELEPHONE AND TELEGRAPH APPARATUS.

607,801. Long-Distance Telephone. Paul de Kilduchevsky, London, England, assignor to the Kilduchevcky Mega-Telephone Syndicate, Limited, same place. Filed Feb. 10, 1897.

MISCELLANEOUS.

607,590. Galvanic Cell. Albrecht Heil, Frankisch, Crumbach, Germany. Filed Dec. 1, 1897.

607,646 Electrolytic Bath. Pascal Marino, Paris, France. Filed Dec. 1, 1896.

607,714. Electric Stop-Motion for Looms. Alejandro Stephens, Guadalajara, Mexico. Filed June 26, 1897.

607,715. Voltmeter. John F. Stevens, Philadelphia, Pa. Filed April 22, 1897. Renewed May 4, 1898.

607,715. Electric Buoy. Ernest W. G C. Hoffmann, Charlottenburg, Germany, assignor to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed May 28, 1896.

607,748. Bond for Electric Conductors. Slaughter W. Huff, Baltimore, Md., assignor of one-half to Jesse Hilles, same place. Filed Aug. 29, 1896.

607,794. Apparatus for Cleaning Paint from Ships. Warren F. Freeman, New York City. Filed June 22, 1897.

TELEPHONE AND TELEGRAPH.

The Boston *News Bureau* asserts that officers of the Erie Telephone Company say that "in no section of the United States has telephone competition by independent companies ever gained a profitable footing. For a while, when free passes are given out liberally and the wires and poles are new and stock is sold locally, there is an appearance of prosperity for the new company, but in a brief time they wither, and under active competition with the Bell forces they die." We have no doubt the officials of the Erie Telephone Company would be glad to have the public believe that this statement of theirs was founded on fact, but everybody knows that there are several independent companies in the West that are doing a successful business and have driven the Bell companies out altogether or compelled them to offer almost free service to retain their footing. In Detroit, Fort Wayne, Des Moines and elsewhere, independent companies have been successfully established, and are gaining ground daily in spite of all the opposition that a powerful and resourceful monopoly has brought to bear against them.

In the New York Supreme Court on the 18th inst., Justice Kellogg filed an order denying an application made on behalf of Simon Sterne for the examination before trial of the officers of the Metropolitan Telephone & Telegraph Company, now the New York Telephone Company, in his suit brought to compel the company to furnish him with telephone service at a reasonable rate. Mr. Sterne recently obtained leave from the court to serve a supplemental complaint on the latter company. An application made by Mr. Sterne for leave to examine the books of the two companies was denied. Justice Kellogg also decided that Mr. Sterne had no case against the New York Telephone Company, saying that it had a right to fix its own rates.

In Des Moines, Ia., it is reported that a regular franchise ordinance for the Iowa Telephone Company is being drafted and will be presented to the city council at an early date. It is proposed to make the telephone company accept the conditions of the ordinance and to bring suits in the State courts to enforce the rates in the event it refuses to comply with it. The maximum charges will, it is said, be fixed at $28 for residence 'phones and $42 for business 'phones. except where long distance or desk instruments are supplied. There will also be a clause to the effect that if the company cuts the rate at any time the lower rate made will thereafter be the maximum rate. A decrease in the rate will also be provided for as the number of 'phones used is increased.

On the night of the 14th inst. off Santiago, the Indiana while raising her anchor found that it had fouled something which on examination proved to be the much hunted after cable running from Santiago to Kingston, Jamaica. The auxiliary cruiser St. Louis and the cable steamer Adria had made many attempts to grapple this cable and cut it, as it was the only remaining line enabling Captain-General Blanco to communicate with Madrid, but their efforts were futile and they finally abandoned the undertaking.

Nearly all the schoolhouses in the Borough of Queens, N. Y., will be fitted with telephones during the summer vacation. According to the plans submitted to the Board of Education the cost for running the Queens system for a year will be $3,500, and the cost of equipping the different buildings with instruments and doing the wiring, etc., will be met by the telephone company. The idea is to have the schools connected by telephone and to have them so arranged that they can be called up from the outside.

The Springfield, Mass., *Union* states that the interest in the new telephone company at Amherst is increasing and quite an amount of additional stock has been sold. A meeting to form an organization will be held at once and after that active steps will be taken. Many letters have been received by local parties recommending the automatic system, and it seems probable that this will be the system adopted if the necessary amount of stock is secured.

At Spartanburg, S.C., the Home Telephone Company has applied for a charter and they expect to organize very soon and begin work. They have nearly 300 subscribers, and propose to connect with twelve to twenty neighboring towns in three or four counties. In many of these towns they will have exclusive connection. They propose to use the very best material and the most improved instruments.

It is stated that the Bell Telephone Company of Philadelphia contemplates increasing its capital stock from $2,000,000 to $4,000,000. A meeting will be called at an early date to take action on the proposed increase.

A despatch to the Burlington *Hawkeye* from Chariton, Ia., states that the Chariton & Newburn Telephone Company has determined on two important extensions of its lines which will be made this year. It will build a line from Lacona to Indianola, having made arrangements for a connection from Indianola into Des Moines. This will give Chariton a direct Des Moines connection.

The Toledo, O., *News* says a syndicate composed of Bowling Green men has purchased George B. Hull's interest in the Harrison Telephone Company. The new owners have elected the following officers and directors: President, L. C. Cole; secretary and general manager, R. E. Connelly; directors: L. C. Cole, John R. Hankey, H. Froney, R. S. Patty, R. E. Connelly.

The New York Telephone Company has published a card giving its rates for telephone service in New York and vicinity. They are: In Manhattan Borough, from $90 a year; in the Bronx, from $40 a year; in Westchester County, from $30 a year. Extension stations are now only $1 a month, with installation charge.

Justice Stover, in the Supreme Court at Brooklyn, N. Y., on the 22d inst., refused a mandamus asked for by J. F. Miniter, to compel the Western Union Telegraph Company to forward a telegram without charging an extra cent for the revenue stamp. Justice Stover's interpretation of the law is that the sender of a message must affix the stamp.

In the quarterly report of the Electric Bureau of the National Board of Fire Underwriters, just out, the statement is made that the number of telephone burnouts and fires from lightning and from various crosses on electric light wires shows the necessity of better protection of signal circuits.

After hearing preliminary arguments of opposing counsel in the injunction suit brought in the U. S. Circuit Court at Detroit, Mich., by the Western Electric Company against the Detroit Telephone Company, Judge Swan gave the attorneys until August 10 to file briefs.

The Washington, D. C., druggists who have sub-postal stations on their premises and who removed their telephones because of a disagreement with the telephone company have been compelled to reinstate the telephones by order of the Post Office Department.

The Erie Telegraph & Telephone Company report an addition of 1,001 subscribers to their system during the three months ending June 30. The total number connected July 1 was 26,693.

In the Philippine Islands there are 720 miles of telegraph, but Manila is the only town that has a telephone system. It is owned by English capitalists.

The Automatic Telephone Company will probably get a franchise in Rochester, N. Y. The committee that has the matter in charge is expected to make a favorable report to the council.

The Colorado Telephone Company has been granted a twenty-year franchise to operate an exchange in Berkeley, Col.

Mayor Warwick has signed the Drawbaugh telephone bill which was passed by the Philadelphia councils recently.

The Western Union Telegraph Company announces that its office at Santiago de Cuba is open for business.

New Companies Incorporated.

The Alvin & Angleton Telephone Company, Alvin, Texas—to operate telephone lines in Brazoria county. Capital stock, $2,000. Incorporators: O. S. Cummings, A. J. Birchfield, F. J. Bush, A. W. Wilkerson and W. A. Leonard.

The Red River Telephone Company, Shreveport, La—to construct a telephone system from Briarfield to Shreveport. Capital stock, $800. President, W. A. Martin; vice-president, J. M. Seutell; secretary and treasurer, R. T. Glassell.

The Sylvan Springs Telephone Company, Clayton, Ill. Capital stock, $1,500. Incorporators: G. L. Thompson, John Padgett and John W. Butz.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 11@11⅛c.; Lake, 11½c.; casting, 11@11⅛c.

The Worcester & Marlboro (Mass.) Street Railway Company has declared a semi-annual dividend of 3 per cent., payable August 1 to stock of record July 25.

The directors of the Wilmington (Del.) City Electric Company have declared a half-yearly dividend of 3½ per cent., payable to stockholders of record July 1.

The American District Telegraph Company of Philadelphia has declared a quarterly dividend of 1 per cent., payable August 15 to stock of record August 5.

The Dry Dock, East Broadway & Battery Railway of New York has declared a quarterly dividend of 1½ per cent., payable August 1. Transfer books reopen August 2.

Ferdinand Peck, of Chicago, has been appointed by the President as Commissioner General of the United States to the Paris Exposition. Chicago will be the headquarters of the Commission.

On the 19th inst., the directors of the Hartford (Conn.) Electric Light Company declared the regular semi-annual dividend of 3 per cent., payable on August 15 to stockholders of record August 1.

The North Jersey Traction Company has sent to Comptroller Gibson of Newark a check for $72,135.74, this being the 5 per cent. franchise tax due the city on its gross earnings. Last year the sum was $67,959.38.

A director of the Manhattan Elevated Railroad, New York, says: "No definite action will be taken in reference to the adoption of electricity until after the franchise question has been settled. When Mr. Gould returns the franchise matter will again be taken up."

The Dallas (Tex.) Consolidated Electric Street Railway has executed a mortgage on all its property to secure the Union Trust Company of St. Louis for the payment of $800,000 worth of bonds just issued and negotiated. The loan is said to be for the purpose of paying outstanding indebtedness and to improve the property of the Consolidated system.

The annual statement of the Union Traction Company of Philadelphia for the year ending June 30 shows: Receipts from all sources, $10,971,437.59, increase $490,791.61; operating expenses, $4,456,375.26, decrease $493,475.18; net receipts, $6,515,062.23, increase $984,266.79; fixed charges and taxes, $6,490,441.75, increase $107,711.38; surplus, $24,620.58.

In addition to the regular dividend and rights to subscribe for additional stock at par, the stockholders of the Edison Electric Illuminating Company of Brooklyn will shortly be informed, says the N. Y. "News Bureau," that the cash surplus in the treasury will be divided before t. e company is transferred to the Kings County Company. The amount is between 3 and 5 per cent.

The Quincy & Boston Street Railway Company, which for the last fiscal year ending September 30 carried 1,200,000 passengers, has made a gain to July 1, 1898, of 247,000 passengers. The last quarter of the fiscal year to September 30 is considered the best quarter of the year. It is therefore estimated the road will carry this fiscal year above 1,500,000 passengers. The company pays 7 per cent. and the balance above this amount is charged off.

The board of directors of the Drawbaugh Telephone Company held a meeting at the office of the company in Philadelphia on Monday, when it was announced that the company is ready to begin operations on the establishment of the new line in that city, although six months is allowed by the ordinance recently passed by councils. Col. J. F. Stokes, president of the company, said that the line would be started just as soon as possible, and it is hoped to get it into operation within a year.

Under the reorganization plan of the Metropolitan West Side Elevated Railway of Chicago the holders of the present $15,000,000 5 per cent. bonds will receive 60 per cent. of the face of their holdings in new 4 per cent. bonds and 53⅓ per cent. of the face (which includes arrears of interest) of old bonds in new 5 per cent. non-cumulative preferred stock. The $15,000,000 of common stock is assessed $4 a share (for which assessment the stockholders will receive new 4 per cent. bonds) and it is scaled 50 per cent. A syndicate has been formed to underwrite the assessment.

The New York State Board of Railroad Commissioners has granted the application of the Nassau Electric Railroad Company (Brooklyn) for permission to increase its capital from $6,000,000 to $15,000,000. The new stock is to be divided into $6,500,000 of 4 per cent. preferred stock and $8,500,000 of common stock. The increase is for the purpose of improving the system by consolidating several railroads into one and providing money for further betterments to the property. The properties which will be included in the new Nassau Railroad system are the same as those which it now operates, but the securities of them all will be now known as Nassau Railroad stock and bonds.

The "Financial Chronicle" states that a director of the Metropolitan Street Railway makes the following explanation regarding the new stock issue to be voted upon August 9: "The public does not seem to have the correct idea about that $15,000,000 of additional stock, apparently believing that $5,000,000 more stock than was at first supposed is to come on the market. Such is not the case. The board thought that as an increase in capital was to be asked for it might as well be $15,000,000 as $10,000,000; $5,000,000 of this, however, will be held in the treasury, in reserve, as announced, and to the best of my knowledge there is no immediate prospect of its being issued therefrom to acquire property, make betterments, or for any purpose whatsoever. The $4,000,000 balance of the $10,000,000 to be issued, over the amount required to retire the scrip, should be sufficient to complete the Sixth and Eighth avenue lines and make the change in the motive power."

A meeting of the stockholders of the Central Traction Company of St. Louis will be held July 30 to increase the capital stock of the company from $100,000 to $5,000,000. John H. Blessing, secretary of the company, says: "This step is necessary in order to provide the large amount needed to build the road. The franchise has been accepted and all the details have been practically arranged, but of course the action must be ratified by the stockholders." The officers of the company are R. M. Snyder of New York, president; John H. Blessing, secretary. The board of directors consists of these officers and Finis E. Marshall, cashier of the Continental Bank of St. Louis; H. S. Potter of Boston, and J. S. Bache of New York.

The fourteenth annual meeting of the Royal Electric Company was held in Montreal, Can., on the 19th inst. The old board of directors was re-elected. The fiscal year ended on May 31 last. The gross amount for the year to credit of the revenue accounts for the business transactions of the company aggregat d $955,826. The expenditure for labor, materials, operation, maintenance and general expenses amounted to $636,057, leaving a gross profit of $319,769. From this is to be deducted interest and fixed charges amounting to $42,609, making an aggregate net profit to the company for the year of $277,160. From this net profit there have been declared four quarterly dividends of 2 per cent. each to the total amount of $120,000.

The Brooklyn "Eagle" says: "Plans for the operation of the consolidated electric light company, which will be composed of the Edison, Kings County and Municipal corporations, are now being discussed by the men in control of these properties. The complete plans have not been decided upon as yet, but as soon as the pending consolidation is formally concluded, which, it is thought, will be about October 1, the entire property will be placed under one management. This, it has been estimated, will result in an annual saving of over $100,000." It is thought more than likely that President Ethan Allen Doty of the Edison Company will be the executive head of the consolidated company.

EDITORIAL NOTES.

The Electrolytic Marine Salts Company.

The Rev. P. F. Jernegan, formerly a Baptist minister but better known as the inventor of an alleged method of extracting gold and silver from sea water and as promoter of the "Electrolytic Marine Salts Company," recently sailed for Europe with a trunk full of Government bonds purchased with cash and under circumstances that were, to say the least, suspicious. What is known as the Electrolytic Marine Salts Company was organized last November under the laws of Maine with a capitalization of $10,000,000 in shares of one dollar each. The company was based on a secret process for which it was claimed that by means of electricity and by the use of a "certain" chemical large quantities of the precious metals could be extracted from the sea water at every tide. A recent issue of the New York *Herald* says:

"In the prospectus the rather blind statement is made that nine-tenths of the stock (of $10,000,000) is held in trust and will be sold for the joint benefit of the discoverers and their associates and the treasury. Another equally blind statement is made that 'Only such proportion of the stock as is actually sold is entitled to retain dividends.'

"The prospectus further says: 'It has purchased from the inventors their processes for the extraction of gold and silver from sea water. These processes are not patented, but they are secret. While it is true that competition cannot seriously injure this company, such is the enormous demand for gold and so great is its commercial start of any similar company that might be formed, it may be noted that its secrets are carefully guarded day and night, the construction of the plant and the character of the employees being such that any successful attempt to discover illicitly its process is foredoomed to failure.'

"Here is a description of the first plant from the prospectus:

"A salt water lagoon, with 49,000 tons capacity each tide, a dam, wharf and grist mill, and two dwelling houses were purchased at North Lubec, Me., and a plant installed. The work was of a new and difficult character. Much of it had to be done between tides and in the night. But it was built quickly, well and cheaply, and began running February 4, 1898.

"At this date the board of directors visited the works and made a two weeks' inspection of them. From nearly a hundred that were in operation, five accumulators were selected that had run a week, and their average extraction of gold proved to be 7.87 dwt. weekly for each. The daily product in gold and silver of each accumulator was in value $1.27. An accumulator run two weeks showed an extraction of 16.1 dwt. gold.

"At the conclusion of the directors' so-called investigation it was said to be their opinion that on a correspondingly larger scale, with 150 accumulators, they could take out $100 worth of gold at an expense of $10—in other words, by May 1 could be producing $2,000 a week net profits. In regard to the secret process the circular says:

"'It is obvious that investors must depend on the veracity of competent witnesses and the accumulation of earnings for their confidence in this process.'"

We have several times referred to this company in our columns, and no later than June 8 made the statement that this scheme should in our opinion be classed in the same category with the Electropoise, electric combs for turning hair from white to black, and with electric shoes, which a firm in England had recently brought out. In another issue, namely that of December 1, 1897, ELECTRICITY also pointed out that what traces of gold and silver there were to be found in sea water were mostly in the form of chlorides and could only be obtained by the most careful and lengthy analyses. Scientists have worked on the problem for years and have utterly failed to devise any method that would pay for itself. Such being the case, was it natural to suppose that a man with little or no scientific training could devise a paying method in the short space of a year or two? Further, if the process devised by the Rev. P. F. Jernegan was such an overwhelming success, why were ten millions of shares of stock issued and placed on the market at the nominal price of a dollar a share, thus offering an extra inducement to people of small means to invest? That there are reputable men connected with the enterprise is not to be doubted, and we understand the stockholders are about to investigate the Rev. P. F. Jernegan's sudden trip to Europe and various other matters.

The New York *Sun* of August 1, in an article from Lubec, Me., dated July 31, says:

"Angry stockholders from all over New England are arriving to investigate the alleged secret process of extracting gold. It is said on the authority of one of the workmen that Jernegan infused gold dust into the mercury accumulators regularly toward the close of each month, resulting in the monthly gold brick. When the accumulators were opened yesterday (July 30), as usual at the close of the month, nothing but seaweeds were found, with slight traces of gold on the accumulators."

The Electric Sugar Refining Company, whose bubble burst so disastrously in 1888, was considered a bad swindle, the much-abused word "electric," as in this case, being used as a bait for the unsuspecting public, but if anything this electrolytic salt water gold scheme may prove even a worse one, as almost $1,000,000 have been invested in it by innocent New Englanders.

Mechanical Draft for Steam Boilers.

In the case of electric lighting plants or other central stations where a large amount of power is generated, the question of providing a suitable draft for the boilers from the standpoint of economy and efficiency is an all-important one. We are in receipt of a paper entitled "Mechanical Draft for Steam Boilers," by Walter B. Snow, which was delivered in the form of a lecture before Sibley College, Cornell University. In this paper the author points out the many advantages possessed by mechanical draft over what is termed "natural draft," and various methods of producing mechanical draft are described. It is pointed out that the chimney as a means of creating a movement of air depends upon the heating of that air by which a difference in density is produced. The heat thus employed is wasted so far as its utilization for any other purpose is concerned. This inherent loss with an ordinary coal, the author states, amounts to about 20 per cent. when the gases are at 500° and the excess of air is 100 per cent. If, he says, in place of the chimney, there be substituted an engine-driven fan of proper size, the resultant of the efficiencies of the steam boiler, the engine and the fan, together with the loss by friction in the apparatus, may be taken at about 4 per cent. Therefore, the work done, or its equivalent in heat units expended to produce the given result, would be about 70 times as great in the case of a chimney as in that of a fan. The paper ends by showing the influence from a commercial standpoint the application of mechanical draft would exert upon a given steam boiler plant equipped with eight boilers of 200 nominal horse power each. This saving in first cost, were the chimney done away with and mechanical draft instituted, is shown to be $11,875. This would indicate an annual saving in fixed charges of about $831. A further saving of $126 a week in fuel would result owing to the fact that an inferior quality of coal could be used with the mechanical draft. In conclusion the author says: "Briefly summarized, mechanical draft has here been shown to be capable of reducing the avoidable losses, of decreasing the first cost of a steam generating plant and of reducing the fuel expense. In addition, it presents certain marked conveniences in the matter of installation and operation. In these days when every step in the process of steam generation and utilization is being scrutinized in the attempt to reduce the cost by even a single per cent., the opportunity presented by the employment of mechanical draft cannot be and is not overlooked."

* * *

Electric Cranes on Shipboard.

Electric motors have been adopted on shipboard but slowly. When first introduced their range of duty was comparatively limited, consisting principally in operating blowers for ventilating purposes, and their application to other uses was unquestionably hindered by the fact that until recently no special marine type of motor was brought out, while the ordinary type of motor was bulky and generally unsuited for the duties it would be called upon to perform. The North German Lloyd line was probably the first transatlantic line of steamers to adopt electric motors on anything like an extensive scale. Their two steamships, Darmstadt and Prinz Heinrich, were equipped with electrically operated winches which proved so successful that when the Bremen of the same line was completed it was fitted with sixteen deck cranes operated by means of electric motors. The thirty-two motors which run the cranes are supplied with current from direct-connected generators, of which there are four of 75 kilowatts each. Two dynamos only are required to operate the sixteen cranes, a third generating set being utilized for lighting, and the fourth is held in reserve. The controlling apparatus, including cranes and motors, is mounted upon a pivoted circular iron platform. The latter is made to revolve by means of a seven horse-power motor running at 700 revolutions per minute, directly coupled to a worm gear which in turn meshes in a gearing fastened to the deck. The total swing outboard on all of these cranes is 20 feet 6 inches. They have a lift of 16 feet 6 inches, the loads being raised by means of a twenty-five horse-power series motor which runs at a speed of 900 revolutions. Two special marine controllers about two feet in height serve to start, stop and regulate the speed of the motors. The mechanism is simplicity itself, for on raising a hand lever the load is raised, while on depressing the same lever the load descends. A movement of the lever either to the right or left causes the crane to turn correspondingly. To insure perfect control, two band brakes are provided, one for each motor, which are attached to an extension of the motor axle and may be operated by a slight pressure of the foot. Two sizes of cranes are in use on the steamer Bremen although both types are similar in form. The larger has a lifting capacity of three tons with a speed of about one foot a second, whereas the smaller has a lifting capacity of but one and one-half tons with a speed of almost two feet a second. In other respects the two sizes are identical and closely resemble each other.

There are many advantages attending the use of electric cranes such as the above on shipboard. One of their most remarkable features, and one that is much to be desired, especially on a passenger ship that is obliged to touch at different ports and unload freight, is their noiselessness of action. Another feature which highly commends them is their simplicity of operation and the ease with which they may be controlled by even the most stupid laborer. Electric cranes are moreover much neater in general appearance and far more cleanly than the crane operated by steam. In all these cranes the electrical mechanism is thoroughly protected against inclement weather, is dust proof and arranged in such a manner that sea water cannot penetrate to it. This type of lift having proven so successful after a lengthy trial on one of the principal transatlantic steamship lines, it should not be long before the electric type of crane is universally adopted for the purpose of loading and unloading our ocean grayhounds.

Under the Searchlight.

Notes and Comments on Various Topics.

THE Boston *News Bureau* of Saturday last, referring to the proposed reduction of the preferred stock of the General Electric Company, says: "Counsel for the committee of preferred stockholders of the General Electric Company have prepared a strong bill which will be filed within a day or two in the United States Circuit Court in Boston or New York, which bill will seek to prevent a carrying out of the directors' plan of a 40 per cent. reduction of the capital stock. The bill will not ask for an injunction restraining the holding of the special meeting called for August 10. The committee points out that the court's decision will be of far-reaching importance, as establishing the rights of minority stock interests in corporation affairs."

* * *

THE Madison (Ind.) Electric Railway Company has appointed five young women conductors on as many of its cars. In selecting the girls the manager seems to have given some attention to the euphonic quality of their names as the list will show. The chosen ones are named Lydia Martin, Addie Douglass, Beatrice Garlinghouse, Rosa Caplinger and Emma Meyer. It has been observed that since these youn women became conductors the cry, "No seat, no fare," has died out in Madison, there being no longer any scarcity of seats in the cars, as the men passengers apparently prefer to stand on the rear platform.

* * *

THE N. Y. *World* says it is "understood that J. P. Morgan and other General Electric men are interested in a street cleaning machine to be operated by electricity. Electrically propelled sweeping and loading carts are to be used. R. N. Beach and W. J. Clark of the General Electric Company are among the incorporators. Authorized capital $1,000,000." There will be a big heap of rubbish to clear away when the General Electric Company dumps its $4,000,000 of patents out of its office, and the electrical street sweeping apparatus of the new company might be tested on that job. If Clark is put in charge of it, he might be able to pick up stuff enough out of the musty refuse to reimburse him for the capital he has invested or expects to invest in the new company.

Can Lightning Strike Through Water?

An interesting fact has come to light regarding the recent explosion of three submarine mines in the Potomac river, which was brought about as was supposed by lightning having struck the switchboard or some of the connections. It now appears that neither the switchboard, cable or electrical connections show marks of having been struck, and General Wilson, who has been investigating the matter, believes, strange as it may seem, that one of the mines was directly struck by lightning through four feet of water and that the others were probably set off by concussion.

* * *

THE very latest development in field telegraphy and telephony consists in a two-horse wagon equipped with four folding tables which when thrown up form desks upon which are placed telephone and telegraph instruments. Batteries are carried beneath the seats, while coils of wire are so arranged as to run out as fast as the wagon is driven. Twenty such vehicles have been ordered by the Government and will be sent to the front as rapidly as possible.

* * *

THE editor of *Lightning*, London, says that he is in receipt of a communication from a lady in Constantinople saying that the reason for the backwardness of matters electrical in Turkey is that the Sultan cannot discriminate between dynamo and dynamite, the second of which he cannot endure.

* * *

Wanted the Frills.

We find the following in the Chicago *Post*:

Of course it didn't happen in Chicago, because we don't have such things here. It happened in a town where they have fenders on the trolley cars—fenders that are designed to pick up the incautious pedestrian, throw him up into the air two or three times and then toss him over the platform railing. Of course, they don't do that, but that is what the agent always insists that they will do, and some of them look as if they might. Anyway the old fellow with the carpet bag evidently thought so. He was standing in the middle of the track when the car came along, going at a rate of a mile a minute or less and clanging its gong at a terrible rate. But he didn't move. Consequently there was nothing for it but to put on the brakes or take chances of having to defend a suit for damages. The car stopped within about two feet of him.

"Get out of the way!" yelled the motorman.

"Come on, consarn ye!" roared back the countryman.

"Get off the track!" shouted the motorman angrily.

"Not much," retorted the countryman determinedly, "I'm waitin' fer ye. Why don't you come on?"

"Do you want to be killed?" demanded the conductor, coming to the front of the car to see what was the matter.

"No, sirree," returned the countryman. "I want to get aboard your blamed old car."

"Well, come on, then," said the conductor, indicating the step at the side of the platform, but the countryman only shook his head.

"You can't work it that way," he asserted doggedly.

"I'm down here to see the hull town, an' you bet I want all the frills. Come on an' hist me now, an' be quick about it."

"H'ist you!" exclaimed the conductor. "Are you crazy?"

"No, I ain't," was the indignant reply, "but I reckon I know my business and can't be put upon by any dern street car man that lives. I've heerd all about your luxurious way of doin' things in the city, an' while I have money in my pocket I'm going to have all the frills an' fixin's there are. You jest come ahead with that there scoop an' pick me up an' put me aboard jest the way you do fer swell city folks or I'll report you to the boss, ding me if I don't."

In another minute he was lying in the wire netting yelling like a Comanche, while the car continued its journey, still at the rate of a mile a minute or less.

* * *

AT Centreport, L. I., a prominent resident recently held a rather novel entertainment for the benefit of the local church in the way of an electrical festival. Electric light wires were run all through the grounds, from which were suspended numerous electric lamps which brilliantly illuminated the dancing platform and rendered the scene very picturesque and attractive.

Petroff or Sir Humphry Davy?

Who was the first to discover the electric light? Our belief up to the present time has been that it was Sir Humphry Davy, in 1813, but *il faut changer cela*, as it now appears that it was Vassili Petroff, a Russian professor, who accomplished the deed in 1802. This is what we read in a note in the Russian edition of the "Cours d'Electricite," by Eric Gerard, which has been inserted by the translator, M. A. Chatelain, who calls it an historic rectification. Almost all the electrical books published on the Continent tell us that Sir Humphry Davy discovered the electric light in 1813, and no one will hesitate in acknowledging that Russia is rather slow in recognizing the services of her scientists, since it took her not less than 96 years to become aware of the existence of the 2,400-cell battery which allowed Petroff to strike the electric arc before Sir Humphry Davy.

THERE SHOULD BE A HOT TIME IN SCHENECTADY ON THE 10TH.

We herewith publish verbatim the interesting document recently issued to the stockholders of the General Electric Company:

SCHENECTADY, N. Y., July 11, 1898.

To the Stockholders of the General Electric Company:

At the last annual meeting of stockholders, held May 10, 1898, the stockholders passed the following vote:

"*Resolved*, That the interests of the stockholders require that any proper or necessary adjustment of the impairment of the capital of the company should be promptly made, with a view to the early resumption of dividends."

At that meeting your Directors stated that while other values were in their opinion conservatively fixed, a revaluation of patents, franchises and good will (which have been kept on its books at substantially $8,000,000 since the organization of the company) should be considered at the proper time.

Your Directors are advised by counsel that in consequence of the impairment of its capital the company is forbidden by the laws of New York to pay any dividend whatever until the amount of such impairment shall have been regained, or until the nominal or share capital stock shall have been reduced to the amount of the actual capital.

Under existing New York law, the nominal or share capital of the company may be reduced at any time by a vote of a majority in interest of all the stockholders, and counsel advise that if any reduction be made the common and preferred shares must be reduced alike.

In view of all the foregoing, your Directors regard it their duty to urge the stockholders to make at once such reduction of the nominal or share capital as shall permit the payment of dividends upon both classes of stock with the least practicable delay.

Appended is the consolidated balance sheet of the company of January 31, 1898 (being the close of the last fiscal year), as it appears in the last annual report of the company. Your Directors, being of the opinion that the valuation at which patents, franchises and good will were carried in this balance sheet—namely, $8,000,000—was excessive, and that the fair and reasonable value of this item is the sum of $1,000,000, have by resolution directed this item to be reduced to that amount upon the books of the company as of June 30, 1898. Taking into account the estimated earnings of the company to August 10, 1898, your directors believe that a reduction of the share capital of the company as of August 10, 1898, to sixty per cent. of its present amount would make the share capital of the company substantially equal to the amount of the net assets which will then be on hand over and above the debts and liabilities of the company. Any surplus net earnings from and after that date will then be applicable to the payment of accrued dividends on the preferred stock and future dividends on both classes of stock.

Your Directors request the stockholders of the company to attend a special meeting to be held at the office of the company, at Schenectady, N. Y., on the tenth day of August, 1898, for the purpose of voting upon a proposition to reduce the company's share capital to 60 per cent. of its present amount as set forth in the accompanying notice. After such reduction each stockholder will hold, for each five shares of stock which he now holds, three shares of the reduced stock of the same class. Your Directors recommend that such reduction of the share capital of the company to 60 per cent. of its present amount be made.

Stockholders who favor the proposed reduction of the capital stock, but are unable to be personally present at such meeting, are asked to sign and return the enclosed proxy at once in the enclosed envelope, addressed to M. F. Westover, Schenectady, N. Y.

By order of the Board of Directors.

C. A. COFFIN, President.

M. F. WESTOVER, Secretary.

A revenue stamp is enclosed to be affixed by you to any proxy you may give. If not used please return the stamp.

Under date of July 28 the committee of preferred stockholders issued the following announcement, which sets forth their idea regarding the proposed reduction in preferred stock:

The committee named in the agreement dated June 1, 1898, between the committee, the American Loan & Trust Company and the depositors of preferred shares, are divided upon the question whether it is for the best interest of the preferred stockholders to acquiesce in the reduction of their shares by 40 per cent., as proposed in the circular signed by the President of the General Electric Company, dated July 11, 1898, Mr. Carr being in favor of accepting the proposition, and a majority of the committee opposed to it. The majority have determined to vote against it and if possible to defeat it by legal proceedings.

Mr. Carr has accordingly resigned from the committee, and the shares represented by him and others as trustees or executors will not be deposited.

Owing to this change of circumstances the remaining members of the committee think it proper to assent, and do hereby assent to the withdrawal by anyone desiring to do so of his shares deposited with the American Loan & Trust Company, upon signifying to said trust company in writing his desire so to do, on or before August 6, 1898, and remitting to said company 12 cents per share, which is the proportionate part of the expenses which have already been incurred.

The shares so withdrawn will be returned to the depositors as soon as possible after the opening of the books of the company.

The undersigned invite the continuance of the deposits of shares already made, as well as further deposits of preferred shares under said agreement of June 1, 1898, with the American Loan & Trust Company, by all who are disposed to join in resisting the proposed reduction of the preferred shares, calling attention to the fact that the liability to expense is limited to one dollar per share plus stamp for transfer as required under the revenue law.

Those who have not yet deposited their shares can do so by mailing to the American Loan & Trust Company the agreement which has already been sent with a circular to preferred shareholders, signed and stamped with a 25 cent revenue stamp (striking out Mr. Carr's name), together with their certificates of stock indorsed in blank.

(Signed) THOMAS L. LIVERMORE, EDWIN F. ATKINS, } Committee.

Help to fight the Electrical Trust by subscribing for ELECTRICITY.

SOME NOTES ON THE ELECTROLYTIC REFINING OF TIN AND THE RECOVERY OF TIN FROM ITS ORES.*

BY SHERARD COWPER-COLES.

Electrolytic methods have recently been applied to the refining of tin, Claus having taken out a patent in which he describes the use of an alkaline solution or compound of solutions containing sulphide or sulphides used for dissolving tin by passing an electric current through anodes cast from the crude tin to be refined. The solution is composed preferably of one part of stannate of sodium and two parts of water. The best results have been obtained from a sulphostannate of sodium (SnS_3Na_2) of specific gravity of 1.070, and heated to approximately 90° C, the current density being approximately ten amperes per square foot of anode surface. The residual metals or other material, except antimony or arsenic, contained in the anode are precipitated as sulphides, together with those metals or residue which are insoluble in the electrolyte. In the case of the metallic tin containing antimony or arsenic, or both, the deposited metallic tin is made the anode in a second bath, which is composed of dilute hydrochloric acid to which hyposulphite of soda has been added, the arsenic and antimony being precipitated as sulphides. Claus has also patented the use of a solution of sulphide of sodium of sp. gr. 1.065; gold, silver, zinc, lead, copper, antimony, iron, etc., remaining insoluble in the anode mud, some as sulphides and some in the metallic form. In some cases the inventor finds it preferable to use hydrate of sodium or potassium, and, instead of smelting the ore and using the alloy as the anode in the electric bath, he finds it more convenient to prepare the sulphostannate of sodium solution by fusing the ore with a proper proportion of sulphur and soda or sulphate of soda and carbon, and lixiviating the mass, or by boiling the ore or other material containing tin in a solution of hyposulphide of sodium and in converting either a part or the whole of the sodium sulphide in the solution into sulphide of ammonium, preferably by sulphate of ammonium or other salts of ammonia, the tin being deposited by an electric current, any copper, bismuth, zinc, etc., present in the tin anodes is recovered in the anode mud. The same method is employed for the treatment of tin ores as that described in the first records of tin smelting, only small improvements having been made in minor details. Attempts have been made from time to time to try and win the tin from the ore by electrolytic treatment. Processes hitherto devised have not been successful on account of the difficulty of finding a suitable solvent for the tin oxide. Dr. Burghardt has proposed treating tin ores electrolytically as follows: The tin ore is first crushed to a powder, to which a sufficient quantity of carbonaceous matter, such as coal or charcoal, is added, varying from 3 to 7 per cent. by weight. A quantity of caustic soda or potash is heated in the vessel without the addition of water, and the mixture of ore and carbon is added to the fused caustic soda, the proportion of caustic alkali being about twice the weight of the ore to be treated. The contents of the vessel are thoroughly stirred until the ores become dissolved and enter into chemical combination with the caustic alkali. The gases driven off by this process are chiefly carbon monoxide and carbon dioxide. The heat is increased until the carbon monoxide ignites. In the process of smelting, the oxide of tin is reduced momentarily to the metallic state; the metal thus formed is at once dissolved in the melted caustic soda or potash forming stannate of sodium. The combination of the ore and caustic alkali having taken place, the contents of the vessel are poured out to cool, and the resulting mass is broken up and dissolved in a suitable proportion of

* From the *Electrical Engineer*, London.

water; the solution is used as a bath in which the tin is obtained by electro-deposition. Vortmann and Spitzer proposed melting finely-pulverized ore mixed with from two to three times its weight of a mixture of one equivalent of sulphur and two equivalents of silver. Air is excluded through the fusion, which results in the formation of a triostannate. This salt is then washed out and the solution is allowed to settle. After the addition of ammonia and ammonium sulphate the clear liquid is electrolyzed with insoluble lead anodes. Classen has also proposed a somewhat similar process for the electro-deposition of tin. The electro-deposition of tin has always been a matter of some difficulty, as the tin has a great tendency to come out in the form of trees instead of in an adherent mass. The electrolyte devised by Roseleur has been used to some extent. The bath is composed of 5,000 parts of distilled water, 50 parts of pyrophosphate of sodium, or potassium, and six parts of protochloride of tin, and is made by placing the pyrophosphate and water in a tin-lined wooden tank, the lining serving as an anode, the stannous chloride being suspended in the liquid in a copper sieve. The first result is to produce a cloudiness in the liquid, which, however, subsequently becomes clear. After the complete solution of the tin in the salt the solution is ready for use. The tin anodes are incapable of keeping the solution up to its original strength in spite of the large anode surface, and small quantities of pyrophosphate tin salt has to be added from time to time. Tin bioxide dissolved in caustic soda has been used to some extent. Maitresse ensures the complete continuity of the tin covering obtained by electro-deposition by heating the coated object to the melting point of tin. All the solutions required for the deposition of tin require to be worked with a moderate current, the voltage being from three to five. The deposits have a dull, frosted appearance, similar to that obtained from silver cyanide solutions, but the tin deposited can readily be brightened either by scratch brushing or by friction of bran or by mopping with lime.

SWITCHBOARD APPARATUS.*

BY J. B. BLAIKIE,

Chief Assistant Electrical Engineer, Bristol, Eng.

(*Concluded from page 37.*)

AMMETERS.

Ammeters for the switchboard should be altogether different from laboratory instruments. The scale should be more accurately readable, at the lowest part, if there is any difference. On a rising load one cannot run too close to the capacity of a machine, while it is of the highest importance that one should know when the load has fallen sufficiently when switching out a machine. Again, when used on circuits, for perhaps 20 hours out of the 24, they are only indicating on the lower part of the scale. In practice they are often subjected to powerful external influences, since it is generally convenient to fix them close to the main omnibus bars. They should therefore be specially protected from such disturbances. The moving parts should be strong enough to stand excessive currents passing momentarily, and for many cases the movement should be damped.

An ideal instrument, if not quite dead-beat, might have a damping arrangement adjustable, so that the necessary amount could be applied under peculiar circumstances. An arrangement of terminals such that a standard instrument could be connected in series by means of flexible leads, to enable the instrument to be checked while in position, would be very convenient. Where a glass cover is used it should be far enough away from the pointer to minimize errors due to static charges on the surface.

The Edgewise pattern is becoming popular now for two reasons: it is more compact as a switchboard fitting, and when fixed in rows, and the index of each standing at a different value, you get a curve formed. The shape of this curve becomes more or less familiar to the attendant, so that he more readily notices a change which may point to an irregularity in the outside system. Ammeters for the exciting circuits of the machines are usually only required for alternators. To make intelligent use of these they should be easily readable through the range of the rheostat. They need not be readable below the minimum current required for excitation. They should be very accurate, well shielded from external influences, dead-beat and strong enough to stand rushes of current when the field is switched on or off.

It is impossible to pass over the subject of ammeters without drawing attention to the Weston instruments. To those not familiar with these, a summary of their advantages may be of interest. Unfortunately they are only suitable for continuous currents. The scale is perfectly uniform throughout the range. The action is remarkably dead-beat. The accuracy is very high, it is independent of external influences, and the calibration is not impaired by comparatively rough usage. The current measured does not pass through the instrument, so that it may be used on any part of the board, the connections being two small wires. It is really a voltmeter, measuring a minute difference of potential across a shunt which is placed in the main circuit. Any number of shunts can be connected by means of small plugs to one instrument. A pretty device, sometimes used with these ammeters, is a luminous scale. The scale is translucent, the gradation lines and figures being opaque. A small lamp fixed behind shows up the reading boldly, so that it may be seen at a distance. The recording ammeter is rarely used, and is perhaps an unnecessary refinement.

Integrating meters, ampere-hour or watt meters are hardly switchboard apparatus at present. They certainly would be useful adjuncts and will probably become general. The usual form of case may be an objection. If the makers would turn out something all over lacquered brass and a reasonable shape, there might be a development in this direction. The same remarks on ammeters with reference to calibrating with a standard instrument might be applied here. The roller form of register instead of dials, in a large size, which could be made of aluminum would be an attractive feature.

VOLTMETERS.

It is most essential that voltmeters should be accurate instruments. They must be sensitive to very small changes and for some classes of work dead-beat. They should be free from temperature errors and capable of continuously indicating the normal pressure for very long periods. They should always be protected by fuses easily accessible. Remarks on ammeters with reference to static charges on glass covers are applicable in some cases.

There are three distinct classes of voltmeters in everyday use—electro-magnetic, electro-static, and those depending on the expansion of a metal due to heat. The electro-magnetic are not available for alternating currents, generally speaking, and except for the purpose of recording instruments, where some power has to be expended in overcoming the friction of the pen on the paper, they do not possess many advantages. The Weston instrument, however, from its dead-beat action and extreme accuracy is again a favorite. As a voltmeter it can be fitted with a luminous scale, and it is usually provided with a movable index in the shape of a disk which eclipses a circular aperture in the pointer. This form of index is very easily seen from a distance. Electrostatic voltmeters are useless for recording, and some forms are liable to stick owing to the very small forces which actuate the pointer. They can, however, be used for alternating and continuous currents, and they consume a minimum of energy. They are most commonly employed for high tension work. Some engineers object to a dangerous potential across an instrument, especially as it has to be observed closely, and frequently tapped to insure a correct reading. A small sparking gap has to be introduced to protect the instrument, and with concentric mains a momentary rise of potential is common and causes the fuses to blow.

The familiar "Cardew" is a most useful instrument, being applicable for continuous and alternating currents and is very dead-beat in action. It gets out of adjustment rather too easily however, and is an awkward shape to accommodate on a switchboard. The horizontal pattern is much steadier than the vertical owing to the steadier rate of cooling. The consumption of energy is rather heavy. In spite of its many defects it is very popular, probably its wide open scale and sensitiveness compare very favorably with rival instruments.

Recording voltmeters are developing and may now render faithful accounts of electrical pressure. But from some points of view they are still imperfect instruments, since they may sometimes ignore the willingness of the spirit whilst testifying to the weakness of the flesh. Where these instruments are used the temptation to tamper with them should be removed, and the interpretation of the charts humane.

RHEOSTATS, MULTIPLE AND FIELD SWITCHES.

Rheostats are often suggestive of the skeleton in the cupboard. They are unsightly and the connections are frequently clumsy even though they may be sound. The choice of resistance material is a matter of great interest. Some alloys possessing excellent qualifications under laboratory tests have been found to have become rotten and brittle after a few years use, or they may suffer mechanical injury during construction either from bending, etc., or heat applied for soldering. Radiating surface should constitute one of the principal features of the design, ventilation being not an unmixed blessing as the more air you get through the rheostat the more dirt and dust is deposited. Compactness is desirable where it can be obtained without sacrificing other advantages. The displacement due to the expansion of the metal while hot must be provided for, and in forms other than the spiral this is rather an awkward matter. Spirals of wire are unsatisfactory since they are liable to shake together and interlock if accidentally displaced. They accumulate a lot of dirt, are inconvenient to clean and also involve comparatively confused connections to the multiple switch. Where a rheostat is only in the field circuit of an exciter and consequently small, it may be wound on a block of slate having a sliding connection along one edge. The slate absorbs a good deal of the heat which can then radiate from the larger surface. It is objectionable to have the contact on the actual wire, as the wear and any slight sparking might in time cause the wire to break. A great advantage, however, can be claimed from the fact that such an arrangement may be fitted on the board always in sight and kept thoroughly clean. An improvement on this form and suitable for larger work is effected by having special contact pieces fitted, and in the use of several small wires in parallel, whereby a large radiating surface is gained. Tubular resistances would be better still, introducing at the same time additional mechanical advantages.

With reference to multiple switches, besides ample current carrying capacity, there must be exceptional provision for wear as this may be very heavy. Circular switches or linear motion derived from a screw are most usual, but as there is a chance of the operator forgetting for the moment which way to turn the handle, it is preferable in the author's opinion to have a lever working through a quadrant in a vertical plane at right angles to the board, the connections being so arranged that the raising of the handle raises the voltage of the machine.

It is sometimes necessary to make fine adjustments and occasionally large alterations rapidly, so that a

* Read before the Municipal Electrical Association, London, June, 1898.

good regulating switch should have two handles, one having a number of intermediate steps between any two steps of the other.

Field switches should always be so arranged that they short circuit the windings at the instant of cutting off the current. The author is acquainted with two designs, one by Messrs. Siemens, the other by the Electric Construction Company, which are well suited for this duty.

SYNCHRONIZING APPARATUS.

In alternating current stations this apparatus is of first importance, and should be the object of the designer's special care and foresight. The possibility of a mistake on the part of the operator should be thoroughly investigated. The risk of breakdown in any part of the apparatus having been reduced to a minimum, provision should be made for replacing any defective detail within a minute or two, with no possible chance of reversing a connection, or there should be a simple method of throwing a spare set into circuit. There have been three or more methods suggested for synchronizing. First, two lamps, or one lamp and a voltmeter in series, off the secondaries of two transformers in series, the primaries being one on each of the pair of leads required to be synchronized. Second, a similar arrangement, having a telephone or buzzer to indicate the flow of current through the secondaries. Third, goldleaf electroscopes which can be used direct on 2,000 volt mains. The first method is almost always employed and it has the advantage of being easily seen by the driver, enabling him to adjust the speed of his engine. This information can also be obtained by lighting the station with alternating current arc lamps. When the armature is at the correct speed, the coil holders appear to be stationary or revolve very slowly forward and backward as the speed is too high or too low. It might be almost worth while to switch on a lamp in broad daylight when synchronizing for this purpose. Where alternate current arc lighting is adopted a goldleaf synchronizer could be used. It is more secure from breakdown for having no transformer. It is very dead-beat, but at present it has not been developed as a switchboard instrument, and requires modification to preserve the extremely high insulation necessary. While on the subject of synchronizing, it is instructive to notice that in English stations an artificial load on the incoming machine is considered unnecessary, although usually employed on the Continent.

In one English station it has been found advantageous to parallel machines through an impedance coil, and then short circuit the coil in two steps. As an extra precaution the paralleling of all machines, up to 400 KW. capacity, is done through a 20 ampere fuse, and this fuse is not blown more than once a month. (It may be mentioned that the armatures are of the coreless type.)

Having discussed the details, the general arrangement and construction of the board may be criticised. Slate or marble are usual as a base; but all holes should be bushed with ebonite, and ebonite plates fixed under all instruments for high tension work. There is a skeleton form, however, made of a lattice work of wood or angle iron on which the various instruments are mounted. This form is highly efficient from many points of view, but in appearance it is untidy, and it occupies a good deal of room. A recent development consists of a number of cells, made by vertical slate partitions fitted into slate shelves, which are built into the wall. In this arrangement there is of course no back, the connections being visible from the front, and carried up through a vertical series of cells.

The commonest form of board is constructed of slate slabs, or panels, having the instruments on the front and all connections at the back. It is the back of such boards that should be most closely watched. It is often necessary to change an instrument, or connect a new machine or feeder, and with high tension current at all points such work is frequently attended with great personal risk. Accumulations of dirt and dust have also to be removed periodically.

Such boards, if designed in a standard panel form, to permit extensions, should also have a standard system of back connections suitably protected, and in no case should miscellaneous cable and wire connections be allowed.

On double pole boards the opposite poles should be far apart, either horizontally or vertically. For the arrangement of omnibus bars and varieties of combinations some reasonable limit should be fixed.

Breakdown terrors are usually more prominent in the minds of high tension engineers, they may stimulate more careful design, but there is also a tendency to run to seed in a progression of combinations. It may be reasonable to have a means of dividing the main omnibus bars, and perhaps have a spare set, sometimes called "hospital bars," for the purpose of connecting any particular circuit, or any particular machine.

With reference to the relative position of the apparatus there is a decided preference for the complete set belonging to one generator, or one feeder being in a vertical line, well marked. It is also advisable to have the lines as close as possible in order that the effect of any adjustment can be watched in the other lines. This principle is so important that where some parts of the apparatus are necessarily large, it might be worth while adding auxiliary gearing to permit of concentration. It is of course essential that the handles of all the controlling gear should be within easy reach, and that the indications of all instruments should be accurately readable from a convenient position.

A necessity or temptation to lean or stretch over any portion of the board should never exist.

It seems almost absurd to mention such an obvious precept, yet it is common enough to find a clock which has to be wound periodically mounted on the top of a switchboard. There are boards protected on the front but this rather encourages carelessness and is often at the expense of safety at the back. By all means guard against every conceivable accident, but under the roof of a central station a board should be assured from wilful misuse or grossly ignorant handling.

A main switch, fuses or other safety device, and ammeter are among the first requisites of a panel, then there may be plug connections, synchronizing connections, field switch and rheostat switch. Voltmeters are usually common to the whole board, and here a suggestion may be borrowed from an American practice, in that of mounting a voltmeter on a swinging bracket from end of the board. It can then be moved to show to the best advantage at that part of the board where an adjustment is being effected.

Field switches may be advantageously mounted on the machine; by this arrangement there is a saving of conductors, and the man who lets down the brushes may be more confident that the machine is not excited at the time. For continuous current machines the rheostat and multiple regulating switch might also be mounted on the machine, or on the wall close by, thereby saving long conductors. Since the electrical pressure regulation is shared between adjustments of excitation and speed, both may be fittingly performed by one man, preferably the driver or dynamo attendant, whose attention can thus be directly called to the brushes at every alteration. Further it can be urged that fire risks are minimized by distributing the rheostats and situating them away from the wood platform or other such work in connection with the switchboard. In the case of alternating current machinery, the rheostat switches at least must be on the board or close at hand.

But there are some alleviations to compensate for the fire risks involved. Alternating current usually means high tension, and the heat generated is of use in keeping the board at a slightly higher temperature than the surrounding atmosphere. There are occasions, when there is a fog, or perhaps in the event of a mishap with steam connections, that this higher temperature may save condensation and consequent troubles.

One of the most pressing considerations in connection with the switchboard as a whole is the efficient protection from dust and accumulations of dirt, especially at the back. Not only should elaborate precautions be taken, but an easy and safe means of inspection and cleaning should be a prominent feature of the design.

From an æsthetic point of view a little license can be granted if all details are well designed. Wood mouldings and paneling add greatly to the general appearance. Some engineers severely cut down anything that is inflammable; this like everything else can be carried to excess. When one considers the proximity of such material to an open fire, in an ordinary dwelling-house, and the small risk one attaches to it, a little ornamentation on a switchboard appears to be reasonable. There is no necessity however to make a switchboard a subject for rococo decoration, and as mentioned before there are fitter places for a clock than in a surmounting scroll.

With a view to standardization another suggestion hails from America. One of the largest firms manufactures unit panels always on a standard size of slate. They make fourteen different capacities on a panel 48 in. by 16 in. by 1½ in. thick, and a blank panel 28 in. by 16 in. by 1½ in. to go underneath. They are bolted onto steel frames and adapted for unlimited extensions. The space required for a switchboard is not of such great importance if correctly estimated when designing the buildings. Too often however it has to go somewhere between two windows, in a cramped position, with little or no room for extensions.

The best position is probably on a gallery extending down the length of the engine room, except in belt or rope driven stations, in which case it should be parallel with the drives to be safe in the event of an accident with the gearing. An elevated position such that the operator can see and signal a driver at the stop valve of any engine is about the ideal.

Though perhaps a little foreign to the subject, a system of engine room signals might be conveniently touched upon here. It is too small a matter to be treated on under its own heading, but at the same time, it is important in the administration of duties from the switchboard. In large concerns a well organized system is indispensable, and in small stations, therefore, unorthodox signs should be considered as bad form. The practice of shouting and cat-calling about an engine room, though it may betoken hearty goodwill and enthusiasm among young assistants and pupils, is to say the least of it, undignified; such cries should be reserved for personal accidents. A regulation whistle or bell, which can be more clearly distinguished from the usual hum, should serve to call the attention of drivers. The number of a machine can be indicated by displacing a tablet having both sides painted the same. If the board can be seen from every stop valve, alterations of speed can be signalled by moving an extended hand and arm "up" or "down," the driver signaling the normal speed by moving his hand rapidly back and forward in a horizontal plane. Where the view is blocked different toned bells or a number of strokes may be employed, but it is remarkable to find how easily such signals can be forgotten or confused after being in daily use for months. Another method is to illuminate a small window, having a word painted on it, by means of a small lamp. Almost any method will answer the purpose provided that it is universal.

Turning once more to the question of standardization, manufacturers have now had the opportunity of gleaning from innumerable specifications, and of silently witnessing some failures. Perhaps a pyscho-

logical treatise on the switchboard attendant is still required.

There are without doubt some curious instances of irregularities due to absence of mind or fatigue. It is not at all uncommon to see a man feel the bearings and fill the oil cups of a standing machine, but when it comes to the switchboard attendant signaling "Raise speed" on a particular engine, the driver adjusting the governor of a standing engine, and the attendant signaling back "All right," the subject becomes decidedly interesting. Then there is the man with the laboratory training, who taps every instrument, including the clock and the almanac, before taking a reading. Fuses and plugs have been pulled out while carrying currents, and there was a story once of the exciting current being switched off an alternator while running in parallel. Possibly designers have already or can easily obtain sufficient information of this description for their guidance.

Once launched on this fascinating theme, ideas and suggestions spring up like mushrooms. In the interest of science let us suppress the prolificacy of imaginations, born of watching and wakefulness in the midnight hours.

Leave such work to professional designers who regard inspirations in the positive degree, and to men who live for "estimating," before whose searching gaze the colors and glories of originality pass and die away.

The author has endeavored to point out the necessity of good standard work for switchboards, and to discourage the individual of designing propensities among "resident engineers." He is aware that much has been done already towards establishing a standard, but has recently received replies to inquiries from several large manufacturing firms, "We have no standard, as we find all specifications differ."

It should be reserved for the resident or consulting engineer to judge, a representative body of engineers to frame rules and regulations, and for designers and manufacturers to perfect details and study economical production.

In conclusion, the author desires to express his thanks to the gentlemen and firms who have rendered him liberal assistance in the preparation of this paper.

ELECTRIC TRACTION.*

BY ROBT. C. QUIN, A.I.E.E.,
B. E. and T. Engineer, Blackpool, Eng.

It goes without saying that the subject of electric traction is so important and extensive that it is impossible to deal with it comprehensively in a paper of this description. The author proposes, therefore, to set forth as briefly as possible the salient points of the subject and to invite discussion upon them, rather than to detail at length any particular system or systems of electric traction.

Road.—In the author's opinion the road, or permanent way, is one of the chief factors which determine the success or failure of any electric traction undertaking, inasmuch as its condition will have a much greater effect upon the maintenance costs, and consequently, the financial result, than would probably be the case with any other system of traction.

Considerable difference of opinion seems to exist as to how this track should be constructed—whether the rails should be 43 lbs. per yard as upon the Giant's Causeway line, or 92 lbs. per yard as upon the Blackpool line—whether the gauge would be 3 feet or standard gauge.

The weight of the rail must of course be proportioned to the weight of the cars running thereon, and to the soil upon which the rails are laid; but it would appear to the author that the present practice errs too much on the side of lightness.

It will be admitted on all hands that smooth running is essential to the longevity of the rolling stock, and that this cannot be attained without rigidity of construction, smoothness of running surface and accuracy of gauge.

In order to ensure these desirable ends it is essential, in the first place, that the track should be well laid on a good solid foundation, accurately gauged and substantially cross-tied. The usual cross-tie for tramway purposes is a $1\frac{1}{2}$ in. by $\frac{1}{2}$ in. strap hammered round at each end and threaded and bolted through the web of the rails; but at Hamburg—at which place it has been the author's privilege to investigate the permanent way construction—things are done on a decidedly better plan. Here the rails, which weigh 106 lbs. per yard, are cross-tied by an I shaped girder, 4 in. deep, which passes under the bottom flanges of both rails, and is secured at each end by two substantial and adjustable chairs. These ties are placed about six feet apart.

The rails also are not butt jointed, but have a half-and-half lap joint, with a longitudinal cut through the web about 10 inches in length. The fishplates securing these are 2 ft. 10 in. long fastened by six $\frac{7}{8}$ in. bolts. The fishplate on the tread side of the rail passes under the bottom flange as far as the web.

This class of rail joint is one which, in the author's opinion, very nearly approaches the ideal. It has unbroken running surface, is rigidly constructed, and has a large rail to rail contact.

The cross-over roads at Hamburg are also of unique construction. At these points the groove of the rail is gradually shallowed until at the actual crossing point it is $\frac{3}{4}$ in. as against $1\frac{1}{4}$ in. at other parts of the rail. The flange of the wheel projects one inch; hence at these points continuity of running surface is attained by riding on the flange of the wheel.

Generator.—Shall it be high speed, slow speed, direct coupled, belt or rope driven; if with the latter shall the flywheel be placed upon the engine or dynamo? are questions which have been ably dealt with in the technical press by Mr. J. S. Raworth. On the question of flywheels, the author begs to state his opinion that the flywheel should be left at the factory, as there is quite sufficient flywheel effect in a tram car. The author further ventures to suggest that what is required is not so much uniform speed of the engine, or uniform E.M.F. of the line, as uniform motion of the tram cars, and in his experience neither of the former is absolutely essential to the attainment of the latter.

Slow speed engines, direct-coupled and belt-driven alike, are doing good service in traction work both in this country and on the Continent. But of these, so far as regards a modern plant, he cannot speak from personal experience. He has within his charge for lighting purposes, however, engines varying in speed from 80 to 5,000 revolutions per minute. The traction plant is of the latter order, i. e., direct-coupled, Parson's steam turbines, electrically governed. These turbines have been working since June, 1897, to the present time and seem well adapted for the purpose. Their efficiency is extremely good, the attention and cost of up-keep extremely small, while the automatic regulation is everything that could be desired.

The extent to which this range of regulation is called upon depends of course in a very large measure upon the weight of the cars, the number of starts per hour, the gradients, and, finally, the starting gear.

MOTORS—GEARING AND STARTING ARRANGEMENTS.

Motors.—The motors for traction purposes should certainly be of the enclosed type, as far as possible watertight, and their capacity such as to enable them on an emergency to develop, for short periods, at least three times their normal power.

The truck carrying the motor or motors should be rigid in construction, flexibility being given solely to the supports of the car body and of the motor.

The efficiency of a traction motor though of course an important point, is not of such great moment as with stationary motors. The question of weight as well as efficiency has to be considered; and the question after all amounts solely to how much power it will require to move the total weight of a car, equipment and passengers, a given distance at a given speed on a given length of track.

The efficiency again should be greatest at certainly not more than three-quarters of the maximum power of the motor, or preferably at its usual working load.

The arrangements for oiling should be such that while giving sufficient lubrication oil should not be able to obtain access to the inner portion of the case. Certain makers of traction motors now cover the bottom coil of the field magnet with sheet lead. This is a good preventive of failure due to the access of moisture, dirt or oil, but it would be better if these could be entirely excluded.

In the author's experience, the weakest point in a traction armature is at the junction of the winding and the commutator. Great flexibility should be allowed at that point, and the armature coils and laminations cannot be too rigidly fixed. The sudden starting with heavy loads on heavy gradients is very apt to spring the windings and snap their connection with the commutator.

There seems at present to be no settled practice as to the number of motors to be fixed upon a car. The author considers, however, that two motors should always be installed—either of which should be sufficiently powerful to take the car home in case the other breaks down. Further, that the starting arrangements should be such that the two motors are placed in series with a resistance and with one another at starting, and that under normal working conditions they should be in parallel, series wound motors of course being used.

The question of gear now appears to be reaching finality but it has passed through many phases. In the early days chain gear was generally adopted with doubtful success. Worm gear followed, but seems now to be gradually giving away before spur gearing.

The tram cars in the author's charge are at present all driven by worm gear. The worms are steel, $4\frac{1}{4}$ pitch, having three parallel threads. The worm wheels are gun metal. The whole is contained in an oil case; the worm is fitted with end thrust ball bearings. Worm gearing, if well fitted, is efficient, but the wear and tear are great, so that it does not long remain in an efficient condition. The worm gear is now being replaced by single reduction gear.

The nature of the controlling gear has an important bearing upon the economic working of a traction system. It has not only an immediate effect upon the revenue account but affects also the life of the motors and of the generators, not to speak of the comfort of the passengers. Moreover, with good controlling starting gear the maximum current taken momentarily by the car is considerably reduced, and with many cars working, and therefore many cars starting simultaneously, the amount of generating plant is most appreciably affected.

Within the author's experience cases have arisen under working conditions of the maximum current being eight times greater than the normal; this of course being with crude starting gear. If this maximum were not to exceed the normal by, say, 50 per cent.—and it certainly need not—the necessary amount of generating plant would be considerably reduced.

As bearing upon the question of the effect of controlling gear upon the life of motors, an incident which happened not very long ago may perhaps point a moral. A certain car, fitted with a series resistance and multiple contact switch as starting gear, stood upon a heavy gradient. The engineer in

*Paper read before the Municipal Electrical Association, London, June, 1898.

charge ventured to start the car, the immediate effect of which was to burn out a motor armature. On a second occasion under similar circumstances he again attempted to start, but this time burnt out the armature of one of the generators. But not to be beaten he repeated the operation under somewhat different conditions. The car was now equipped with a series parallel controller, the motors being the same. On this occasion he was successful as on all subsequent occasions when this experiment was tried.

Cars.—Double-deck cars are almost invariably used in England for urban tramway purposes. The practice, however, on the Continent is just the reverse. With the exception of Paris, single-deck cars seem to be the rule. The correct size of a car and the number of passengers it should carry are questions which cannot be settled until the conditions of traffic are known. If the line is double throughout a large number of cars can be conveniently worked. If it is a single line and loops the workable number of cars becomes limited, and their capacity therefore must be proportioned to the requirements of the traffic.

If the amount of traffic varies within wide limits during certain portions of the day, or at certain seasons of the year, it would appear to the author advisable to attach trailers to the motor cars at those times rather than to carry a heavy dead load of car weight the whole time.

While on this point the author would suggest that some better unit of efficient working might be established than the cost per "car mile." What is a car mile? Is it a trailer car carrying 15 passengers and weighing 3 to 4 tons; a motor car carrying 30 passengers and weighing 7 to 8 tons; or a motor car carrying 80 to 90 passengers and weighing anything up to 23 tons? He would suggest "ton mile" as a better unit.

System of Feed.—The preceding remarks apply with equal force to all methods of electric traction, but the most debatable feature in the question is the means to be adopted of conveying the energy from the generator to the motor.

The trend of technical as also of public opinion in this country appears to be in favor of overhead. It is, the author believes, admitted by all that it is the cheapest method, but some have qualms as to its sightliness and safety. These points it is obvious with a little skill and forethought can be easily provided for.

Strong posts of ornamental construction are now obtainable, and when used for the joint purpose of lighting the street and supporting the overhead conductor cannot be objected to by the most critical.

The overhead line must always be in evidence, but it is remarkable how accustomed one can become to it, so much so as not even to notice its presence.

The best means of ensuring safety is good work, first-class materials and sound construction. The gauge of the trolley line should not be less than 000 S. W. G., although 0 (B. & S.) appears to be the general thing on the Continent.

Two overhead conductors should be provided even for single line and loops, being, the author considers, cheaper in the end than spring frogs and other expedients.

Section blocks should not under any circumstances be placed in curves, also they should be provided (when trolleys are used) with guard checks to prevent the trolley wheel jumping the line when passing.

The span wire system of support appears best suited to high rates of speed, and is convenient in narrow streets where supports can be attached to the houses, but it necessitates a great number of straining wires at curves, which are not sightly.

The life of the overhead line is greatly affected by the class of contact making apparatus which is employed. Certainly the life appears longer with the rolling wheel than with the sliding bar. Whether the advantage which the bar has at curves and junctions sufficiently compensates for this, the author cannot say.

With a trolley line well erected and fitted with guard checks at cross-overs and junction frogs, there should be little risk of the trolley wheel jumping the line, but nevertheless such a contingency must be provided for. In the first place, the trolley head when free from the line should not be able to rise to any great extent from its working position. In the second place, should it happen that the trolley jumps the line when the car is proceeding at high speed and the head of the trolley locks against one of the supports (either bracket arm or span wire) something must give way. What will prove to be the weakest link cannot of course be given for certainty, but should it happen to be the trolley standard, accidents are likely to occur. The author suggests that it would be best to provide the weakest link in the shape of a loose trolley head, and that this trolley head should be anchored by an insulated cord to the trolley arm, say three feet from the top end. The only result then of the locking of the trolley head would be its dropping free from the arm.

It is necessary where telephone or telegraph wires cross the overhead conductor to provide some means for preventing these wires, in the event of their falling, from making contact with the overhead conductor. There are two ways of doing this: the first is to fix an insulator such as a wood or other moulding on the top of the conductor at those points; the second to suspend above the trolley line one or more guard wires. These latter seem to be preferable, as in practice the wood moulding works loose and makes considerable noise by vibration when the cars are passing. The guard wires should be stranded and capable of withstanding as great a stress as the trolley line itself. They should, the author also considers, be efficiently connected to earth. If this is so, a telephone wire coming in contact with the overhead line and the guard wire causes a short circuit and a cut-out at the generating station.

With overhead systems a rail return is almost invariably used, and therefore the question of bonding and of the earth circuit should be considered at this point.

For all practical purposes the conduction from rail to rail by fishplates and bolts must be neglected, and it becomes necessary to provide electrical bonds across these rail joints of the same equivalent area as the rail.

The rails the author is now using have an area equivalent to a square inch of copper. The bonds consequently should have this section. Under these circumstances it is preferable to use two bonds, as one of a square inch section would be inconvenient.

The heads of the bonds should have a contact area of at least 2½ square inches, and should be of such construction as not to render them liable to work slack. It is a good thing in calculating the fall of potential upon a given line to allow 20 per cent. for increased resistance due to the slackening of the bonds. Even with this bonding, unless the disposition of the gas and water mains has been carefully considered, the Board of Trade limit of stray earth current is likely to be exceeded.

If a gas or water main crosses the track or approaches the vicinity thereof, and from that point takes a shorter route to the neighborhood of the station earth than do the tramway rails, or has along that line of route a less resistance than the corresponding tramway return, it will take a greater proportion of current than is allowable; then, parallel to that gas or water main, an insulated conductor should be laid from the point of tramway rails above mentioned to the negative terminal of the dynamo.

Conduit.—The local conditions necessary for the successful working of a conduit system are, the author considers, freedom from sand and mud on the roads, good drainage and a wide slot. The conductor should not be visible from the surface of the street and should be frequently supported on insulators. It is necessary to have a wide groove in order to obtain an efficient form of collector or plough, as not only has it to contain the insulated conductors, but it must also be mechanically strong. The groove of the conduit should in all cases be parallel to the lines, and the conductor should not be co tinued across the points or cross-overs, as in these cases it would necessarily be exposed.

Generally conduits contain two insulated conductors, and this to the author seems preferable. It cannot be said that conduit systems have up to the present been successful enough to warrant their general adoption. Recently the author inspected four different conduit systems, but only two of these were then working.

The initial cost of a conduit system varies from 30 to 200 per cent. in excess of the cost of an overhead system, and the up-keep even where the conditions are favorable is about 10 per cent. greater than the overhead.

Accumulators.—The accumulator system of traction certainly possesses very great advantages, the principal of which is that the service of cars is not dependent on the maintenance of one system of feed, each car being entirely independent; but we have carefully to consider at what cost this independence is obtained. The crux of the whole question is the cost of carrying a useful load of passengers a certain distance, and for this purpose it is well to see how the question is affected by the adoption of storage cells. There are three heads under which additional expenditure is entailed—first, the interest upon the additional capital required for the installation of the cells and also their depreciation; second, the cost of propelling the additional dead load; third, the inefficiency of the cells.

With cars running all day with one charge the weight and cost of cells are both very great, as a comparison of the cars used in Dresden for overhead line only and of the cars at Charlottenburg for accumulators will testify. Dresden cars carrying forty passengers weigh eight tons; Charlottenburg cars carrying forty-two passengers weigh twenty-three tons. In both cases the useful load of passengers is approximately three tons. The cost of the accumulators used on the latter cars is about £750 per car.

The cost of traction accumulators varies from £75 to £125 per ton, the former figure being for rapid charging and discharging short-distance cells.

The author was much interested in the statements made by Mr. Epstein in his Institution paper (on the authority, he believes, of the Hanover Tramway Company) that the cost of the accumulator system of working there was only .2d. per car mile greater than the overhead system, and he must confess when making his recent visit to Hanover he did so with the intention of ascertaining how that .2d. was arrived at. To a certain extent he was unsuccessful, the cost of the up keep of the cells not being obtainable; but he believes that the figures which he has obtained are sufficient to effectually disprove that statement.

There is in Hanover one line of rather less than ten miles worked entirely by accumulators, the cars working that line being also equipped by the overhead, so that they are interchangeable with cars working on the combined system. They weigh 11½ tons and carry 36 passengers. The time occupied in running this journey exclusive of charging and stoppages is 45 minutes. The cells are charged at two stations en route, at one of which eight minutes charge is given at constant potential and at the other twenty-five minutes. The accumulators are placed under the seats, each car being fitted with 208 cells of Tudor type, and there are three plates in each cell. The weight of these cells is approximately two tons, and the installation cost of each car £200. The energy taken per car mile on this track was 1.5 units.

Although the up-keep cost of the cells was not ob-

tainable, the average life of the cells was given at about 18 months, and moreover additional cars have to be provided on the accumulator line as several cars are always occupied charging.

There is also another line at Hanover worked on the overhead system. Here the cars carry thirty-two passengers and weigh six tons. The energy taken per car mile of these latter cars was .68 units.

On the combined overhead and accumulator system, with cars similar to those in use on the accumulator line, the energy taken per car mile was 1.37 units.

Leaving the initial cost of the accumulators out of the question, there is the effect on the revenue account to be considered.

With rapid-charging low-capacity cells (which are really the only ones worth considering), the weight of cells for a five miles journey with one charge is about one ton for every 3¼ tons of car and passengers. Therefore with a car and passenger load of thirteen tons we must have four tons of accumulators. As every ton mile on a given road requires the same expenditure of energy, it follows that the energy given to the motors to propel this car will have to be increased approximately 30 per cent.

Opinions differ as to the efficiency of these cells, but generally the users of them consider that the watt-hour efficiency is about 60 per cent., and the author does not think the figure is far wrong. Therefore the energy of charging these car-carried cells has to be increased 117 per cent. owing to their inefficiency and weight. Further, the wear and tear of the road and cars is increased by the additional weight.

The life of the plates of the cells is variously given by the users as from one to two years, by the representatives of the makers as from two to three years; but the majority of the users do not find much difference between the li e of positive and negative plates. The cost of the up-keep of cells is given by the various tramway companies using them at from ¾d. to 3½d. per car mile, and the author thinks a fair average may be taken at 1½d. Assuming the cost of current to be .75d. per unit, and .7 of a unit to be taken without cells, figures the author does not think advocates of accumulators will cavil at, the cost of energy with the overhead system would amount to .325 penny, and with accumulators to 1.14 pence, or an additional cost of .62d.

This added to 1½d. for the up-keep of the cells per car mile gives us the additional cost of 2.12 pence, neglecting the extra wear and tear of the cars and road.

Now consider the capital cost. The overhead system per mile of double track costs complete, including bonding of the rails, steel posts (on span wire or bracket system) about £1,600. If these posts are used for street lighting purposes, the cost of the posts should be divided equally under the two heads, reducing the overhead cost to £1,000 per mile of double track; with a 2½ minute service and cars traveling eight miles per hour there will be six cars on the mile section, and, with the weight of the accumulators given, each car would cost £300 to equip, or £1,800 per mile of double track.

Again, if charging stations were adopted with say fifteen minutes charge, six additional cars would be required at an additional cost per mile of £560, making altogether a sum of £2,360 per mile.

With a slow service of cars the initial cost of the accumulators would probably be less than the overhead, but the additional cost of 2.12 pence per car mile (with only twenty thousand miles per car per annum) capitalized is equivalent to the sum of £3,530, bearing 5 per cent. interest for each car running.

COMBINED SYSTEMS.

Various combinations of the three systems before enumerated have been adopted. More generally it is a combination of the overhead line and accumulator system, but in all cases of which the author has cognizance, the adoption of accumulator systems has been not a matter of choice but of necessity.

When the necessity arises, the author would desire to point out most strongly that the dead load of the car in proportion to its useful load should be as small as is compatible with stability of structure. That arrangements should be made that the additional dead load of the accumulators is carried only so far as is absolutely necessary. It is therefore advisable to so arrange the battery that it can be detached as a whole from the car at the junction from the overhead line.

A great deal has been said from time to time as to the effect of the acid upon the cars and trucks, and of the odor of sulphuric acid which pervades the cars when the cells are placed under the seats. From what the author has seen of modern systems constructed on these lines he can give his assurance that these complaints are not well founded; and, if it were not for the inconvenience of detaching the battery as a whole from the car under these circumstances, he would certainly recommend the cells being placed beneath the seats.

Where the conditions are such as would permit of the working of a conduit system, and in the absence of permission to use the overhead, the author considers the combination of overhead and conduit much more preferable than the use of accumulators. The additional weight carried is negligible and the the working cost decidedly lower than with accumulators.

There have been many attempts to devise improved methods of electric traction, to obviate the disadvantages of the systems above enumerated, but they, one and all, have drawbacks peculiarly their own, which have hitherto prevented their general adoption. The names of these systems are legion.

The conclusions arrived at by the author all tend to the opinion that in the present state of electric traction engineering there is but one good and reliable and cheap system, and that is the overhead. Where a combination is necessary and conditions are favorable, overhead and conduit combined comes next in order of merit. That as at present constructed accumulators are not, from a commercial point of view, a satisfactory solution of the traction problem.

THE ELECTROCHEMICAL BEHAVIOR OF CHROMIUM.*

Chromium is a metal which until lately has been prepared in small quantity and a state of only approximate purity. It is now freely obtainable by reduction of its oxide in the electric furnace, or, better still, by the use of aluminum according to the method which has been the outcome of the experiments by various chemists, notably Vautin; this method has been put on a manufacturing footing at Krupp's works at Essen. Since chromium became procurable in the massive state Prof. Hittorf has investigated its electrochemical properties, and he has communicated an account of his observations to the German Electrochemical Society at their annual meeting recently held at Leipsic.

It might be expected on general chemical grounds that chromium would behave as an electro-positive metal similar to zinc, but Prof. Hittorf found that in dilute acid solutions in the cold not only is no hydrogen given off, but the chromium is electronegative to such metals as copper, mercury and silver. In the same way it fails to reduce such metals from solutions of their neutral salts and behaves generally as an inert "noble" metal. On making chromium an anode in cold dilute acids it indeed dissolves, but not with the formation of chromous or chromic salts; it passes at once to the state of chromic acid. The oxidation takes place quantitatively fairly in accordance with Faraday's law; the fact that the loss of weight of the anode is rather greater than the value calculated from the current passing is to be accounted for by the presence of impurities in the specimen of chromium used, which contained 3.5 per cent. of iron, about 0.1 per cent. of silicon and a trace of manganese; these foreign substances were probably derived from the aluminum used in the reduction of the chromic oxide to metallic chromium.

When chromium is made the anode in a fused salt as electrolyte, such as potassium bromide or zinc chloride, it behaves very differently. The metal goes into solution as chromous chloride, again obeying Faraday's law, but under these conditions dissolving three times as fast as in aqueous solutions. This behavior is evidently related to the property which chromium possesses of reducing salts, such as the chlorides of cadmium, lead and silver, when heated with them in the anhydrous state, while it fails to reduce them in aqueous solution. On raising the temperature of the electrolyte to 100° C. certain salts, even in aqueous solution, dissolve an anode of chromium as a chromous salt; such salts are barium chloride and ammonium chloride. Potassium bromide, cyanide and fluoride, on the other hand, dissolve a chromium anode as chromic acid at a temperature of 100° C. These remarkable alterations of behavior are most conveniently illustrated by the use of zinc chloride, which, on account of its great affinity for water and low melting point, can be caused to pass imperceptibly from a s ate of solution to one of igneous fusion. Thus, as the solution of zinc chloride is concentrated, its boiling point rises, and the chromium anode, which at the ordinary temperature dissolves as chromic acid, begins at 130° C. to dissolve as a chromous salt. [The author does not state whether at any intermediate point the chromium dissolves as a chromic salt.] A further curious observation is that, quite apart from its properties when used as an electrode, chromium which, as stated above, will not reduce solutions of the chlorides of copper, gold, palladium and platinum, even at boiling temperature, can be caused to do so by the addition of a salt of the class of potassium or sodium chloride. The smaller the quantity of this excitant which is added the more slowly does the reduction occur. Correlation with the electrochemical phenomena is established by the fact that only such salts as permit the dissolution of an anode of chromium as a chromous salt below the boiling point of the solution suffice to bring about the re duction; salts such as zinc chloride, which in aqueous solution at 100° C. still allow the formation of chromic acid from a chromium anode, do not act as excitants.

A natural outcome of these properties, which is nevertheless surprising at first sight, is that when chromium is made the anode in a hot solution of such a salt as KCl containing an easily reducible salt, viz., $CuCl_2$, metallic copper is separated *at the anode*. Rather more chromium is dissolved than corresponds with the current used, and it is presumably this surplus which effects the reduction of the copper. In short, the electrical arrangement, i.e., the use of the chromium as an anode, may be regarded as an artifice to induce the dissolution of the chromium to achromous salt, i.e., to act as a powerful reducing agent.

A study of the EMF. developed by chromium in KCl against Ag in $AgNO_3$ (with $NaNO_3$ as an intermediary) shows that at low temperatures, say 6° C. to 30° C., the EMF. is inconsiderable, but that it rises rapidly at 50° C., and at 100° C. is as high as 1.006 volts. The more dilute the solution of the electrolyte (KCl) surrounding the chromium the higher is the temperature at which a large increase of EMF. occurs. Returning to the chemical side of the question, one finds that certain of those salts which even at the boiling temperature are not reduced by chromium are reduced when the experiment is conducted under pressure, and the temperature of the solution is thus

*From the *Electrician*, London.

correspondingly raised. Thus at 225° C. $CuCl_2$ solution when heated with chromium deposits copper; at 195° C. $PdCl_2$ deposits palladium. Still more noteworthy is the tendency of the chromium when once it has been rendered active by any of the procedures given above, to persist in that condition after the *causa causans* has been removed. For example, when the galvanic combination $CrKClNaNO_3 AgNO_3Ag$, which is brought into activity by being raised to the boiling temperature, is allowed to cool, its activity may persist at the lower temperature. This persistence is more marked when the chromium is brought into contact with a halogen compound at a still higher temperature, e.g., chromium which has been exposed to the action of fused zinc chloride generally retains, although it has been duly cleansed, its capability of acting as an electro-positive metal, provided that the test be made with a galvanometer having a high resistance—30,000 ohms, for example. When it is allowed to yield a perceptible current, by cutting down the resistance of the galvanometer, it soon reverts to the inactive condition; the change is still more speedily induced by making the chromium the anode in an electrolytic cell.

The dissolution of chromium with the production of a chromic salt instead of a chromous salt on the one hand, and chromic acid on the other, which was adverted to above, can be accomplished by making chromium the anode in an alcoholic solution of zinc chloride at the ordinary temperature. With such a combination the chromium dissolves in close concordance with the requirements of Faraday's law, the electro-chemical equivalent of Cr for this combination being $\frac{52.5}{3}$.

The whole matter, as far as the facts are concerned, is excellently summarized by the author: Chromium can dissolve electrolytically in any one of its three states, according to the nature of the electrolyte and its temperature. Its inactive state, corresponding perhaps with the passive state of iron, appears to be the most stable of the three. The attainment of this passive state is not to be attributed to the presence on the metal of a thin layer of oxide, a hypothesis which is plausible for iron. It appears rather to imply that the surface at least of the metal differs in its molecular arrangement according to the conditions and surroundings to which it is exposed; in short, that chromium appears to be an allotropic element, using that much abused word for want of a better. The whole inquiry is of exceeding interest, and may we hope be profitably pursued by its present able investigator.

Meeting of the American Electro-Therapeutic Association.

The Eighth Annual Meeting of the American Electro-Therapeutic Association will be held on September 13, 14 and 15 at the Hotel Iroquois, Buffalo, N. Y. At this gathering a large number of important papers will be read, and an illustrated lecture on the X-ray will be delivered by Dr. Wm. J. Morton of New York.

An excursion for members, exhibitors and friends from New York to Niagara Falls and return, with stop over privileges at Buffalo, will leave the Hoboken Depot of the Delaware, Lackawanna & Western Railway on Monday morning, September 12, reaching Buffalo about 7 P. M.; a palace car will be attached. Tickets for the excursion, good for thirty days, to return on any regular train of the Delaware, Lackawanna & Western Railway, $10; seat in palace car, $1.50 extra. Tickets and seats can be secured from Dr. Robert Newman, 64 West 36th street, New York, from whom all particulars may be obtained. Early application should be made, for if a sufficient number can be secured a special train will be run. Special hotel rates at Niagara Falls will be secured for all excursionists.

LONDON NOTES.

[From our London Correspondent.]

Competition in Electric Lighting.

For some weeks past the English electrical world has been troubled with the question whether a municipal authority shall be allowed to set up electricity works and supply consumers in direct competition with an electric lighting company to which it allowed Parliamentary powers to be granted years previously. The Board of Trade allowed powers to two London Vestries for such a purpose and the shares of all the London electric lighting companies fell very heavily, and there was a good deal of concern as to what the future was going to bring forth. A Parliamentary committee having the final settlement of the matter has however since thrown out one of the orders, thereby leading to the opinion that after all competition was not to be allowed. In consequence electric lighting shares soon rose in value to about their former prices. Up to the present if a local authority has desired to go in for municipal electric lighting, it has had to purchase the existing works of a company at a very high premium, but there is now a very strong effort being made to render it possible for them to put down an entirely separate undertaking and compete with the company on its own ground. Such a course would, to say the least of it, not be just, as the companies secured their concessions years ago under the impression that they would have monopolies, and be bought out by the councils at any time the towns or districts desired upon special terms, or at certain periods upon better terms for the municipalities. One effect of the situation is a movement on the part of certain companies to endeavor to secure powers from Parliament to go into districts where municipal plants are operating and compete with them. There seems every prospect that such permission will not be granted.

Patent Litigation.

The Castner-Kellner Alkali Company, Limited, has just been claiming, before Mr. Justice Bigham in the Chancery Division of the London High Courts of Justice, an injunction to restrain the Commercial Development Corporation from manufacturing or selling any caustic soda or other alkali in infringement of the letters patent granted to Carl Kellner, No. 20,259, of 1894, for an alleged invention of improvements in electrolytic apparatus for decomposing metallic salts. The plaintiffs claimed damages for sales made under the infringement. The defendant company denied the infringement, and said that the alleged invention was not new or useful, and that it was not proper subject matter for letters patent. The letters patent were asserted to be invalid, and a number of patents were quoted in proof of prior publication. Mr. Fletcher Moulton, Q. C., Mr. Bonsfield, Q. C., and other eminent counsel whose names are generally associated with the great electrical patent cases, were for the plaintiff, and Mr. Terrell, Q. C., and Mr. Astbury, Q. C., and others appeared for the defendants. After hearing a great deal of technical evidence (among those appearing on one side or the other were Lord Kelvin, Mr. James Swinburne, Mr. Dugald Clerk, Mr. G. Grindle, Prof. C. Vernon Boys and Mr. Rhodin, inventor of the defendant's patent), the Judge said he would deliver judgment shortly.

Independent Telephone Association of Michigan.

The annual meeting of this association was held at Grand Rapids on the 26th ult.

The most important business of the meeting was the discussion of rates and the thorough review of the present situation of the wires of the companies of the State with especial reference to points between Muskegon and Indiana and between Grand Rapids and Detroit. A satisfactory conclusion was reached by the companies represented, so that it is entirely probable that active operations will be entered into immediately to complete the wires. Detroit was reported by E. H. Parker to have over 5,600 telephones in operation, with some 20 toll line connections on the New State Telephone Company's lines. This company is building several exchanges, the largest being in Jackson. Its long distance copper wire reaches Lansing this week and Grand Rapids soon. The Saginaw Valley was reported by R. F. Johnson with exchanges at Flint and Bay City; the Saginaw exchange will begin service with a total of 1,800 telephones. Grand Rapids reported 2,400 telephones and 282 State line connections; Kalamazoo, 700 telephones; Lansing, 650; Muskegon, 450. A large number of smaller exchanges bring the total number of independent telephones up to some 16,000, which is 2,000 more than the Bell Company has in the State.

Arrangements were made to connect the various toll systems together and also to connect with the Indiana and Ohio toll systems by long distance lines, and the prospects for Chicago and Indianapolis connections on or before January are favorable. The following officers were elected:

President—J. B. Ware of Grand Rapids.

Vice-Presidents—W. L. Holmes of Detroit, C. K. Monroe of South Haven, Geo. W. Finch of Escanaba.

Secretary—Alexander McLeod of Detroit.

Treasurer—W. H. Fildew of St. Johns.

Executive Council—The President, Secretary, Treasurer, F. B. Johnson of Lansing, R. F. Johnson of Saginaw, J. Williams of Adrian, Hugh Park of Muskegon, W. C. Osborne of Kalamazoo, P. H. Parker of Detroit.

At the meeting were present, in addition to the local exchange, representatives of all the larger exchanges and toll line companies, including those in the Detroit, Saginaw Valley, Lansing, Kalamazoo, St. Johns, Owosso, Oceana, Montcalm, Stanton and southwest sections of the State.

CANADIAN NOTES.

A proposal is to be made to the city council of St. John, N. B., to secure legislation to take over the property, privileges and franchises of the St. John Electric Street Railway Company, to be conducted by the city in the interests of ratepayers.

The project to produce power by the construction of a channel from the Welland to the Jordan river, Ont., has again been revived. Mr. Wm. Pearson, C. E., of Oswego, is said to have pronounced the scheme feasible from an engineering standpoint. The question of disposing of the power will now be tested.

The Canadian Pacific Railway Company having completed their new copper wire between Ontario and the Pacific Coast are now able to give better facilities, and consequently have reduced their rates 20 per cent. from Ontario to many of their offices in British Columbia.

Ex-Mayor Elliott, of Brantford, Ont., representing the syndicate which has undertaken the construction of the proposed new railway between Brantford and the city of Woodstock, has just been conferring with Toronto members of the syndicate respecting arrangements for an early start in building the road. D. A. Middleton, C. E., of Ottawa, has just completed a survey of the road, which traverses as fine a stretch of agricultural country as is to be found in Canada, and is particularly adapted for railway construction, the average per mile of cost of construction being about ten per cent. less than the ordinary estimate. The new line will be 26 miles in length. It is expected that active operations will commence on the 1st of September next.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

LEGAL NOTES.

At Hartford, Conn., on the 26th ult., a transcript was sent to the Court of Appeals in the case of the Electric Car Company of America and Thomson-Houston Electric Company against the Hartford & West Hartford Railroad Company.

The Western Union Telegraph Company has secured from Judge Purnell at Raleigh, N. C., an order restraining the Railway Commission from enforcing its order of 1897 making the rate on messages 15 cents for ten words from point to point in North Carolina, and its order of the last month making the rate on messages 24 cents in case the company makes the sender pay for the revenue stamp. The restraining order was served on Railway Commissioner Abbott, and will be heard before Judge Purnell at Raleigh the first Monday in September.

The Cincinnati *Enquirer* of the 23d ult. contains the following: "Col. T. C. Campbell, Guy Mallon and other attorneys have been taking depositions in this city during the past two days in the case of Green, Joyce & Co. of Columbus, O., against the Columbus Central Street Railway Company. The object of the inquiry is to establish the ownership of $350,000 of stock in the street railway by the First and Second National Banks of this city. The stock is now in the names of Lee Anderson, a colored porter, and Edward Morgan, a colored messenger in W. E. Hutton's brokerage establishment on Third street. Both are entirely insolvent, and it is alleged that the banks named are the true owners of the stock. The Columbus Central Road is in debt to the amount of $200,000, and its assets are valued at $530,000. Under the statute of liabilities the banks can be held for 100 cents on the dollar if their ownership is proved. Thomas McDougall is representing the banks. Judge George B. Okey of Columbus has been appointed Master Commissioner in the case by the court in that city."

In Philadelphia on the 26th ult. two suits were begun in the Common Pleas Court by the city of Philadelphia against the Philadelphia Standard Telephone & Telegraph Company as principal, and the Chestnut Street Trust & Saving Fund Company as surety, to recover damages for the failure of the telephone company to put in operation within one year from the date of the approval of its plans, July 23, 1896, a system to accommodate 2,000 telephones in the city, and also for failing to construct, lay and maintain a system of cables, wires and electric conductors. The suits are brought on two bonds given by the telephone company, conditioned for payment of $50,000 each, with the trust company as surety, for the faithful performance of the contract entered into with the city.

Meeting of the American Society of Civil Engineers.

The Thirtieth Annual Convention of the American Society of Civil Engineers was held in Detroit on July 26, 27, 28 and 29. In the absence of Mayor Maybury, the Rev. C. L. Arnold made the welcoming address, in which he touched on what science had accomplished and cited instances of engineering feats as old as civilization itself, such as the seven great wonders of the world. The engineers and the members of the organization he had the honor to welcome were, he said, the executors of the dreams and theories of the past.

In the annual address of President Fteley he reviewed in a general way what had been accomplished in engineering, and especially in railway construction, etc., during the preceding year. The United States, he said, had only 41 per cent. of the railroad mileage of the world in '96, as compared with 43 per cent. at the close of the year in '92. The general tendency of railroad business during the past year had been toward increase of speed and safety, through the block system of signals, through the perfection of the equipment and through efforts to secure uniformity in mechanical devices. Notable progress had been made especially in the abolition of grade crossings. The development of cable and electric railways had been phenomenal, and compressed air as a means of locomotion had also come to the front, while the electric locomotive was no longer a matter of experiment.

He further touched upon the canal question and reviewed exhaustively bridge structure, hydraulic dredging, dock and water works construction, tunneling, sewer construction and the advance in the development of electricity producing plants and hydraulic engineering. The address was most enthusiastically received. During the Convention the following papers were read and discussed:

"Experiments on the Flow of Water in the Six-foot Steel and Wood Pipe Line of the Pioneer Electric Power Company at Ogden, Utah," by Charles D. Marx, Charles B. Wing and Leander M. Hoskins.

"The Determination of the Safe Working Stress for Railway Bridges of Wrought Iron and Steel," by E. Herbert Stone.

"Marine Wood Borers," by Charles H. Snow.

"Dredges and Dredging on the Mississippi River," by J. A. Ockerson.

"Reservoir System of the Great Lakes of the St. Lawrence Basin; its relation to the problem of improving the navigation of these bodies of water and their connecting channels," by Capt. Hiram M. Chittenden, U. S. A., with a mathematical analysis of the influence of reservoirs upon stream flow, by James A. Sedden.

"Three-hinged Masonry Arches: long spans especially considered," by David A. Molitor.

The social feature of the Convention was everything that could be desired, and several pleasant outings such as trolley and boat rides were enjoyed.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING PLANTS.

Cresco, Ia.—This town has just voted by a handsome majority to put in an electric light plant.

Duluth, Minn.—City Engineer McGilvray has submitted to the council an estimate of the cost of a 500 arc light plant. The estimate makes the cost per lamp for all night service at $55.42. His figures for labor, etc., are as follows: Assistant superintendent and electrician, $1,200; engineer, $1,080; oiler, $720; two firemen, $1,440; two linemen, $1,800; three trimmers, $2,160; coal, $6,250; carbon, $4,450; incidentals, $600; depreciation of plant, $4,450; interest at 4 per cent., $3,560; total, $27,710.

Eaton Rapids, Mich.—A. R. Welch of Chelsea has been granted a five-year contract to light the city with electricity. Thirty arc lights are to be furnished at $40 each per year.

Grand Forks, N. D.—The city council acting on a petition from two-thirds of the qualified voters has made an appropriation for the installation and equipment of an electric light plant.

Greencastle, Md.—The town council has granted George F. Bloser a franchise for an electric light plant, and he will form a company for the purpose of building and operating the plant as soon as possible.

Harriman, Tenn.—The workmen have finished setting the poles for the new electric light plant that is to furnich illumination for this town.

Livingston, Mont.—The electric light plant of this city was almost entirely destroyed by fire on the 24th ult. Loss, $32,000; insurance, $24,000. The plant was the property of the Livingston Water Power Company. It will be replaced at once.

Mt. Pleasant, Tex.—Davis Bros. are making arrangements to put in a 400-light dynamo and electric light plant in this place and expect to have the plant in operation by September 1.

North Manchester, Ind.—The North Manchester Electric Light Company has made a proposition to the town council to buy its plant, and the latter has the offer under consideration. The company proposes to turn the property over to the town for $23,800, payable in twenty semi-annual installments, with 5 per cent. on the deferred payments.

Pittsburg, Pa.—Morris Mead, superintendent of the Bureau of Electricity, promises something great in the way of an electrical display during the approaching conclave of the Knights Templars. Supt. Mead is at work on the designs for the display, and he says they will be of such a character as to surprise and astonish the visitors to the conclave.

Portchester, N. Y.—The Portchester Electric Light Company has completed its organization, and is having plans prepared for a plant to be erected as soon as possible. The capital stock of the company is $50,000.

Redlands, Cal.—The Redlands Electric Light & Power Company has issued $300,000 additional capital stock, making the whole issue $500,000. The increase was made for the purpose of paying off the obligations of the company and perfecting the works.

Sacramento, Cal.—The water is so low in the American river at Folsom that power for the operation of the dynamos cannot be obtained for the works there and the lighting and street car service of this city has been interrupted. The old local power plant has been brought into requisition and the cars and lights are kept going.

West Superior, Wis.—Mayor Dietrich has ordered that all the street lights of the Water, Light & Power Company and fixtures be removed from the streets. The clerk has been instructed to advertise for bids for the lighting of the city by arc and naphtha lights, it being the opinion that a great saving will result to the city as a result of this step. The action is taken by the mayor and the council as a result of the city and lighting company being unable to agree on prices for lighting the city.

STREET RAILWAYS.

Alton, Ill.—The promoters of the new electric road to connect Alton with East St. Louis and with some small towns en route, have effected an organization by electing the officers and directors as follows: President, C. E. Carroll, St. Louis; vice-president, J. A. Meblin, Cleveland, O.; secretary and treasurer, A. Hothaus, St. Louis; directors: the officers and W. M. Warnock of Edwardsville, and Manning Mayfield of Alton.

Anderson, Ind.—The formal transfer of the property of the Anderson Street Railway Company to the Union Traction Company was made on the 22d ult. by Congressman Henry. The consideration was $300,000. In this transfer the Union Traction Company pays $150,000 cash and assumes the bonded debt of $150,000. The latter has filed a mortgage to the Farmers' Loan & Trust Company of New York, covering the property. The amount of the mortgage is $600,000.

Bristol, Conn.—The town council has been informed by Vice-President Ingleson of the New York, New Haven & Hartford Railroad, that active operations are to begin at once towards equipping the Providence, Warren & Bristol branch of the road with electricity. The cars will be equipped with trolleys as preferable to the third-rail plan for this line.

Brooklyn, N. Y.—The Brooklyn Elevated Railway has begun running its new electric motor cars on its tracks through the city.

Buffalo, N. Y.—The State Railroad Commissioners have granted the Buffalo Valley Railroad Company permission to construct an electric railroad from this city to Java, 26 miles distant. The road will be equipped for freight and passengers. E. E. Felton, president of the Pennsylvania Steel Company of Steelton, Pa., is president of the company.

Canton, O.—The Stark Electric Railway Company has notified the city council that the work of construction is about to begin under the franchise which has been granted to it.

Clinton, N. Y.—The Sauquoit Valley Electric Railroad Company has made application to the board of trustees for permission to construct and operate a street railway in this village.

Dayton, O.—The franchise which was granted to the Dayton & Troy Railroad Company by the county commissioners has been revoked, the date fixed for a commencement having expired.—A new inter-urban electric railway company has been organized under the name of the Rapid Transit Company, and proposes to construct a line between Dayton and Xenia. J. W. Neff, of Xenia, is the vice-president and one of the leading spirits in the company.

Dallas, Tex.—Ex-Mayor F. P. Holland is reported to have made the announcement that "the most extensive scheme of electrical railways ever projected in the South or Southwest has been planned to radiate from Dallas to neighboring towns and cities within a radius of 50 miles. William H. McGrath, vice-president and general manager of the Dallas Electric Company, is now in Boston to interest capitalists and is said to have secured several million dollars cash ready for investment in the enterprise. Charters will be procured from the State for the construction of lines from Dallas to Fort Worth, 32 miles; Dallas to Waxahachie, 30 miles; Dallas to Denton, 30 miles; Dallas to Greenville, 30 miles; Dallas to McKinney, 30 miles. The Waxahachie line may be extended to Corsica, 54 miles from Dallas, and to Hillsboro, 75 miles, and the McKinney line to Sherman and Dennison, 60 and 75 miles respectively from Dallas. The men who have the enterprise in hand usually carry through anything they take hold of. Mr. McGrath represents in Dallas and Texas already approximately $10,000,000 of Northern financial interests."

Frederick, Md.—A preliminary survey of the proposed route of the Frederick, Thurmont & Northern Electric Railway, and a report thereon, together with an estimate of the cost, will be submitted at a meeting of the directors to be held in this city August 3.

Iowa, City, Ia.—An electric street railway will probably be built here at an early day as parties are figuring on the cost, etc., and the rapid growth of the city is an encouraging factor.

Jackson, Miss.—General Carnes, who has a franchise for an electric road here, left the city for Memphis a few days ago and on his return, within a fortnight, will, he said, give immediate attention to the building of the road so as to complete it before the expiration of the time agreed on with the city council.

Millbury, Mass.—The franchises for a new electric road from Grafton, through North Grafton and Millbury Junction, have been granted, and the work of construction will be begun at once. The line will be about ten miles long.

Nevada, Mo.—An electric street railway is being built here by an Eastern syndicate who are pushing the work so as to have cars in operation by the last of August.

New York.—The work on the new underground trolley lines in Sixth and Eighth avenues is being rapidly pushed. About three thousand men are now employed on the task, and they are divided in three shifts of eight hours each, so that there is not an hour, day or night, when the work is stopped. The officials of the road say they see no reason why at the specified time, September 15, the whole work should not be completed and the new system in operation.

Pittsburg, Pa.—The Penn avenue car barns of the Consolidated Traction Company were completely gutted by fire on the 24th ult. On the second floor were stored forty-eight winter cars worth $55,000. These were entirely destroyed. A special car intended by the company for the use of President C. L. Magee and private parties was being built in the car shops. It was about finished at a cost of $5,000, and was burned with three other special cars. The company's loss was about $175,000, but is fully covered by insurance.

Quincy, Ill.—Judge Allen of the United States Court at Springfield has issued an order granting a temporary injunction restraining the J. C. Hubinger Company from constructing or operating an electric railway in certain streets in the city of Quincy. The order was issued on complaint of the Quincy Horse Railway & Carrying Company.

Redlands, Cal.—Steps are being taken for transforming the present horse car line of the Redlands Street Railway Company into an up-to-date electric line. Bonds are to be issued for the purpose. H. Fischer, J. H. Fischer and O. H. Childs have purchased a controlling interest in the company.

Savannah, Ga.—The "News" says: "The movement toward a new street railway in Savannah seems to be taking definite form. New York parties, who are largely interested in electrical enterprises, are understood to be pushing the matter, and if the outlook appears satisfactory may come into the field and give Savannah the benefit of competition."

Stamford, Conn.—The Consolidated Railroad's branch line between Stamford and New Canaan has been changed to a trolley line and the steam cars have been withdrawn.

Tiverton, R. I.—There seems to be a general demand for an electric road between Tiverton and Seaconnet, and those in a position to know are of the opinion that the road will soon be built.

TRANSMISSION PLANTS.

Columbia, Pa.—The large dam of the Susquehanna & Tidewater Canal Company spanning the Susquehanna river at Wrightsville has been leased for ninety-nine years to the Mastic Water & Electric Power Company. The company paid $75,000 for the lease and have executed a mortgage for $400,000. The water wheels and motors will be located in a building along the canal. About $25,000 will be spent in repairing the dam. Power will be furnished to Lancaster, York, Columbia and neighboring towns.

Fresno, Cal.—The San Joaquin Electric Company's plant is unable to furnish power or light on account of the scarcity of water in the San Joaquin river. This is one of the largest transmission lines in the world. It was recently built. J. S. Eastwood, vice-president of the company, has returned from a trip to the power plant thirty-five miles east of this city. He found a great shortage of water in the mountains, as many of the streams have dried up. The snow has disappeared and the springs have quit running. The north fork of the San Joaquin, where the power plant is located, is low, and the big reservoir some twenty-five miles further back in the hills affords but little water. The company promises to make some arrangement to supply its customers with light, and it is believed it will take hold of the old electric light company's plant and put it in condition.

Lowville, N. Y.—The village board has granted a franchise to Lafayette Wetmore to set poles and string wires within the corporation limits for the purpose of supplying electricity for light and power. Mr. Wetmore proposes to erect a plant on the Beaver river at Belfort and transmit electricity to Lowville and other points. He intends to organize a stock company to carry his project into effect.

MANUFACTURING, ETC.

Fort Wayne, Ind.—The Fort Wayne Electric Corporation has been successful in securing the services of Mr. A. J. Churchward, so long connected with the Excelsior Company, as electrical engineer. Mr. Churchward is generally known throughout the United States on his great success with single-phase alternating motors and rotary transformers, his latest patented device being a unique brushholder which the Government has adopted as standard. The Fort Wayne people are to be congratulated. It is understood that so soon as their new factory is completed they will enter extensively into transmission work.

Middletown, Conn.—C. E. Dustin, who was at one time connected with the Schuyler Electric Company, is endeavoring to interest our business men in a plant for the manufacture of electrical supplies which he proposes to establish here if sufficient encouragement is offered.

Pittsburg, Pa.—The electrical equipment of what is proposed to be the largest copper-refining plant in the United States, now in course of erection at Perth Amboy, N. J., by the Raritan Copper Works, has been awarded to the Westinghouse Electric & Manufacturing Company.

Washington, D. C.—United States Consul Wilburn at Dublin, Ireland, writes that a Health Congress is to be held in that city in August, the subjects to be discussed being the disposal of refuse, water supply of cities, treatment of sewage, sanitary inspection, regulation of plumbing, etc. An exhibition of articles relating to public and domestic hygiene, sewage disposal, drainage, heating, lighting and ventilating apparatus, electrical apparatus, etc., is to be held in conjunction with the congress.

COMPANY MATTERS.

Mansfield, O.—S. N. Ford, one of the largest stockholders of the Card Electric Company, has been appointed receiver of that concern on motion of the Citizens' National Bank and others, whose claims aggregate over $25,000. The company was organized in 1893 with a capital stock of $100,000. It manufactured car motors and other electrical appliances. The receiver was authorized to continue the business, as there is considerable unfinished machinery at the works and orders amounting to about $20,000.

Harrisburg, Pa.—The steam and street railway companies of the State have been notified by the State Railway Bureau that they must report before September or they will be certified to the Attorney General's department as delinquents and made to pay the penalty of $5,000. Last year there were several delinquents and proceedings were taken against them. The Bureau has been notified by ex-Congressman James Kerr, of Clearfield, that the Northampton Street Railway Company, organized a few years ago by New York and Clearfield capitalists to build an electric railway between Easton and Bethlehem, has passed out of existence. It was capitalized at $200,000. On the 23d ult. Judge Simonton made an order on application of the Attorney General revoking the charters of the Crawford Junction & McKean Street Railway Company, Daguscahonda & Elk Railway Company, Clarion Railroad Company and Brockwayville & Daguscahonda Railway Company.

ELECTRICIANS IN THE WAR.

Peekskill, N. Y.—The 1st Regiment of Volunteer Engineers is now full and expects marching orders at any moment. They were hoping to leave on the 3d inst., but there seems now to be some doubt of this. Their destination, when called upon, will probably be Porto Rico. Col. Eugene Griffin is said to be very proud of his regiment, and would like them to take some active part in the war before it is brought to a close.

PERSONAL AND MISCELLANEA.

A Minneapolis dentist has been apprehended on a warrant issued on a complaint of the Minneapolis General Electric Company. It is charged that the dentist arranged connection with the main wires of the company so that the electricity for use in his suite of four rooms would not be registered by the meter. He had many appliances of an up-to-date nature which require power to operate them and he used electricity for that purpose. The small amount registered on his meter led to suspicions which an investigation proved were well founded and hence the suit. Under the new electrical law of the State such an offence is punishable by fine not exceeding $500, or five years in prison.

Oliver W. Kenney, superintendent of the Weston (Mass.) electric power station, was killed on the night of the 22d ult. The storm had disarranged the fire alarm system and Mr. Kenney went to the battery room of the town hall for the purpose of locating the difficulty. While there he touched a live electric light wire heavily charged. Death was almost instantaneous.

RECENT COMPANY ELECTIONS.

Bethel Electric Light & Power Company, Bethel, Vt.—Directors: S. M. Washburn, M. Moody, E. Davis, M. G. Safford, L. M. Heath, W. H. Creamer and Rollin Gilson.

City Railway Company, Wilmington, Del.—Directors: O. W. Clark, S. W. Colton, Jr., Preston Lea, E. W. Clark, Jr., C. Ford Stevens, W. W. Pusey and Thomas C. Barr.

Galesburg Electric Motor Company, Galesburg, Ill.—President, Fred Secord; vice-president, Robert Chappell; secretary and treasurer, Loren Stevens; directors: Fred Seacord, Wilkins Seacord, Robert Chappell, P. M. Johnson, B. F. Arnold, J. K. Mitchell, Loren Stevens, O. F. Price and George L. Price.

Harrisburg Traction Company, Harrisburg, Pa.—Directors: E. C. Felton, Edward Bailey, David Fleming, James M. Cameron, Benjamin F. Myers, Henry A. Kelker, Henry M. Kelley, E. Z. Wallower, A. G. Knisely, F. Eugene Walz, C. L. Brinser, S. F. Dunkie, George W. Reilly, Jr., E. W. S. Parthemore, T. G. Calder.

Colorado Springs Gas & Electric Company, Colorado Springs, Col.—Directors: Irving Howbert, J. Humphrey, F. H. Morley, J. A. Hayes, W. P. Bonbright, R. J. Bolles and W. J. Copeland.

Middletown Electric Light Company, Middletown, Conn.—President, D. Ward Northrop; secretary and treasurer, H. L. Mansfield; general manager, L. O. Whitney; directors: D. W. Northrop, W. T. Elmer, W. H. Barrows, H. R. Butler, James P. Stow, Henry Woodward and Henry L. Mansfield.

Orange & Passaic Valley Railroad Company, Orange, N. J.—President, Col. Charles A. Sterling; vice-president, William Scheerer; secretary and treasurer, John H. Ely.

Portchester Electric Light Company, Portchester, N. Y.—President, William E. Ward; vice-president, Addison Johnston; treasurer, William E. Ward; secretary, Walter Comly.

COMMERCIAL PARAGRAPHS.

It is something unusual for the maker of an incandescent lamp to be willing to guarantee the maintenance of initial candle power for 800 hours or for approximately one-half the life of the lamp. This however is what the Beacon Lamp Company of New Brunswick, N. J., are willing to do, as will be seen elsewhere by their notice in this issue. Furthermore, as this concern offers samples for testing, it must feel assured that it can accomplish what it guarantees. The Beacon Lamp Company also offers for sale something new in the way of a 2.75 watts lamp. Any persons contemplating purchasing incandescent lamps would do well to send the Beacon Lamp Company a trial order.

We would call our readers' attention to the advertisement of the Reading Electrical Manufacturing Company of 739 Penn street, Reading, Pa., which appears in this issue. This concern is prepared to sell gas and gasoline engines, dynamos or motors, voltmeters and ammeters—in short almost any electrical apparatus desired—at a very moderate price. Any one contemplating investing in apparatus of the above description would do well to write the Reading Electrical Manufacturing Company and procure their price list.

The American Impulse Wheel Company of New York state that they are making steady headway with their improved water wheel and that it is attracting considerable attention in this and foreign countries. The company report that they have the most satisfactory commendations in every instance and find business increasing rapidly. Besides wheels shipped to various parts of the United States and reported giving most favorable results, the company have wheels installed in Japan, France, Sweden and Scotland. Among contemplated large power and transmission plants in Canada, Utah, Montana and Minnesota, the wheels of the company are being given most serious consideration, and their adoption in several instances, as per advices now in hand, is confidently expected. The company claim they have all the advantages in their water wheel of the best heretofore in the market, with added improvement as the result of the latest scientific knowledge and test. They claim to spare no pains to perfect mechanical design and construction, together with the highest efficiency, and give special attention to regulation. Mr. Thorburn Reid is consulting engineer of the company.

INCORPORATIONS.

The Electro-Magnetic Weighing Scale Company, Sacramento, Cal.—to manufacture, buy and sell automatic electro-magnetic weighing scales, etc. Capital stock, $1,000,000. Directors: H. G. Smith, W. P. Owens, F. B. Smith and Edward Hanak.

The Paris Light & Power Company, Paris, Tex.—to manufacture gas and electricity for light, heat and power. Capital stock, $60,000. Incorporators: D. H. Scott, B. J. Baldwin, Jr., F. J. Record and John A. Porter.

The Union Electric Company, Camden, N. J.—to generate and sell electric current for heat, light and power. Capital stock, $6,000. Incorporators: H. George Lewis, Oak Lane, Pa.; Charles J. Hart, Sharon Hill, Pa.; H. G. Kepler, Charles H. Hagy and John F. McCarthy, Philadelphia.

The American Electrocure Company of Vineland, N. J.—to manufacture and sell electrical appliances for curative purposes. Capital stock, $100,000. Incorporators: Benjamin F. Ladd, Eli B. Hendee, George Davidson and others, all of Vineland.

The Spartanburg Gas, Electric Light & Street Railway Company, Spartanburg, S. C. Capital stock, $200,000. Incorporators: William E. Lown, George G. Day and Albert Leszynsky.

The Tippecanoe Electric Railroad Company, Monticello, Ind.—to construct an electric railway from Monticello to Rochester, to Fowler and to Covington—length 110 miles. Capital stock, $50,000. Incorporators: Monticello—Henry

Van Voorst, Laughry Bros., J. E. Hanneway, L. G. Gustauel, J. W. Jost, Emory B. Sellers, Martin Witz, E. R. Dye, William Spencer, E. R. Gardner, W. H. Hamelle, F. B. Hamston, C. C. Spencer; Buffalo, Ind.—F. A. Ewing, Owen Kitchen; Pulaski—C. L. Bader, S. March; Headlee—Dennis P. Teeter.

The Natchez Light, Power & Transit Company, Natchez, Miss. Capital stock, $200,000. Incorporators: Maurice Mase and others.

The Dayton & Northern Ohio Railroad Company, Dayton, O.—to build and operate an electric railway between Dayton and Troy, linking Chambersburg, Vandalia and Tippecanoe. Capital stock, $10,000. Incorporators: James Christy, Jr., H. E. Randall, W. C. Shepherd, F. J. J. Stout and C. E. Hoover.

The Union Electric Company, Bridgeport, N. J.—to conduct a general electric business. Capital stock, $6,000. Incorporators: H. George Lewis, Charles J. Harr, H. G. Kepler, Charles H. Hagey, Joseph F. McCarthy and Samuel H. Richards, of Bridgeport.

The Cleveland Electric Light & Power Company, Cleveland, Tenn. Capital stock, $10,000. Incorporators: W. W. Cunningham, Frank Spurlock, Foster V. Brown, John O. Ramsey and C. A. Danals.

The Indianapolis Storage Battery Company, Indianapolis, Ind.—to manufacture storage batteries, electrical machinery and horseless carriages. Capital stock, $100,000. Incorporators: Charles F. Smith, Loren S. Dow and Anthony J. Wilson.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JULY 26, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

607,852. Brake. Ernst W. G. C. Hoffmann, Charlottenburg, Germany, assignor to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed Dec. 29, 1897.

607,918. Crossover for Trolley Systems. Charles E. Davis, Chicago, Ill., assignor to the Link-Belt Machinery Company, same place. Filed Nov. 21, 1896.

607,919. Electric Tramway. Alfredo Diatto, Turin, Italy. Filed Dec. 1, 1896.

608,088. Insulated Rail-Joint. George A. Weber, New York City. Filed Nov. 5, 1897.

607,901. Car-Fender. Albert C. Woodworth, Providence, R. I., assignor to the Consolidated Car Fender Company, same place. Filed April 12, 1897.

607,954. Car-Fender. John W. Range, Providence, R. I., assignor to the Consolidated Car Fender Company, same place. Filed June 16, 1897.

607,977. Car-Fender. Warren W. Annable, Grand Rapids, Mich., assignor to the Consolidated Car Fender Company, Providence, R. I. Filed Jan. 10, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

608,109. Electric Light for Surgical Purposes. Willard E. Dow, Braintree, Mass. Filed March 26, 1897.

ELECTRICAL MACHINERY AND APPARATUS.

608,013. Reversing-Rheostat. Imle E. Storey, Philadelphia, Pa. Filed Jan 29, 1898.

608,133. Means for Preventing Stray Magnetism in Dynamo-Electric Machines. John F. Kelly, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company of Massachusetts. Filed May 27, 1898.

608,134. Electrical-Circuit Controller. Robert Lundell, New York City, assignor of two-thirds to the Interior Conduit & Insulation Company, same place. Filed Feb. 1, 1898.

608,135. Commutator-Brush Holder for Dynamo-Electric Machines. Robert Lundell, New York City, assignor of two-thirds to the Interior Conduit & Insulation Company, same place. Filed Feb. 4, 1898.

608,137. Electromotor for Electrically Propelled Vehicles. Alexander Siemens, London, England, assignor to Siemens Bros. & Co., Limited, same place. Filed Nov. 18, 1897.

TELEPHONE AND TELEGRAPH APPARATUS.

607,994. Microphone. Thomas J. Howell, London, England. Filed Jan. 3, 1898.

608,076. Electric-Telephone System for Houses. Louis Piaut, New York City, assignor of two-thirds to Elias Koch and Alphonse Koch, same place. Filed Sept. 9, 1897.

MISCELLANEOUS.

607,830. Device for Operating Electric Switches. James H. Cary, Springfield, Mass. Filed Jan. 8, 1896.

607,921. Electrical Measuring Instrument. George E. Elphinstone, London, and Arthur C. Heap, Penn, England. Filed May 13, 1898.

607,984. Magnetic Ore-Separator. Gerald J. Crean, Montreal, Canada. Filed Jan. 7, 1898.

607,989. Interior Conduit. Eric E. Erickson and Frederick W. Erickson, Boston, Mass. Filed June 3, 1898.

607,992. Igniter for Gas-Engines. Ralph B. Hain, Grand Rapids, Mich., assignor to the Monitor Vapor Engine & Power Company, same place. Filed April 8, 1896.

607,997. Electrically-Self-Propelling Vehicle. Louis Kreiger, Paris, France. Filed March 11, 1897.

608,015. Secondary Battery. Georg Walter, Strasburg, Germany. Filed Aug. 19, 1897.

608,100. Annunciator Gas-Fixture. John L. Bixby, Arlington, Mass., assignor to Nathaniel Conant, Brookline, Mass. Filed Nov. 26, 1897.

608,104. Electric Sounding Device for Ships. John P. Buckley, New Orleans, La. Filed Dec. 11, 1897.

608,132. Electrostatic Measuring Instrument. John F. Kelly, Pittsfield, Mass. Filed April 14, 1898.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

TELEPHONE AND TELEGRAPH.

According to the statement of a railroad officer, the long distance telephone has ruined the business of one of the limited trains between New York and Chicago, and this, he adds, "is not surprising when it is remembered that the limited service was designed chiefly for those who were obliged to make quick business trips and could not afford to be absent more than a few days from their headquarters. With them time was money, but now they are able to accomplish their business over the telephone at a decidedly less expense than when they had to travel back and forth between the centers of trade mentioned. Therefore, they no longer have need of a fast train service. It is not the broker and the merchant alone who find the telephone a valuable means of quick communication. All the larger railroad systems are using the long distance wire and economizing time, while also not infrequently escaping vexation of mind and spirit due to misunderstanding and delay. Railroad officers who formerly were obliged to spend many hours on the road that could have been utilized to advantage in their offices, or had to use the telegraph wires, can now remain double the time in their offices that they did and talk with subordinates along the line, securing from personal conversation over the long distance 'phone much more prompt and satisfactory results."

The decision of the United States Circuit Court in the case of the Western Electric Company vs. the Millheim Electric Telephone Company et al., of Pennsylvania, in favor of the complainant, is being exploited as a great victory for the Bell Company as it sustains letters patent No. 449,106, issued March 31, 1891, to John J. Carty of the New York Telephone Company for a bridging bell on party lines. The defence was lack of novelty and patentability. This decision, however, is of minor importance, and only affects some small independent telephone companies operating in rural districts where more than two instruments are connected in a single telephone circuit. These have been obliged to use the bridging bell in order to give satisfactory service to their subscribers. In large cities or thickly populated districts the decision will have no bearing, as independent companies have found it more economical to furnish each subscriber with an independent line, or to connect at the most two instruments in a single circuit. The Millheim company is but a comparatively insignificant company, and was probably unable to put up much of a defence, nevertheless the case will, we understand, be carried to a higher court.

The Chesapeake & Potomac Telephone Company of Washington, D. C., has a number of suits on its hands because it refuses to supply service at the rate ($50) prescribed in the bill making appropriations for the District of Columbia, which was passed by Congress at the recent session. The law took effect July 1. One of the suits has been heard by Judge Hagner and taken under advisement. The telephone company set up as the grounds for refusing to observe the law: 1. That it was unequal and unjust in its operations, compelling every subscriber to pay the same amount for his telephone, irrespective of the use he made of it. 2. That it applied only to the telephones used by the District Government, not to those of the public generally. 3. That it violates the constitutional guarantee against the confiscation of property, in that the rate prescribed will not pay operating expenses and a fair return on the investment of money in the plant.

To obviate the use of the usual conductors in burglar alarm systems for safes, vaults, etc., Mr. Clyde Coleman of Chicago has invented a system of employing Hertzian waves. In accordance with this invention, the connecting conductors are entirely dispensed with and a transmitter is provided in the protected structure which is thrown into operation immediately upon any tampering with the protecting barrier, so as to produce a series of vibrations capable of transmission through the intervening medium to actuate a cohering receiver at the alarm station. The receiver closes the local alarm circuit, causing the bell or other means to produce a signal, until the attendant stops it by decohering the particles between the electrodes.

The Kinloch Telephone Company has begun operating in St. Louis. An officer of the company says: "The number of 'phones in use will be increased gradually, as the girls become proficient, until by September 1 we will have 5,800 in operation. The Kinloch Company has laid 331,000 feet of underground cable, strung 436,000 feet of aerial cable, and used up 2,270 miles of copper wire. We have up to-date 5,800 subscribers, and 4,082 telephones have been connected and are ready for use when the switchboard is operated. The switchboard will be handled by 115 central girls. We have 246 men employed in the cable work, and 430 working in the basement and constructing the switchboard."

The Hudson River Telephone Company has completed a very important addition to its system in a new line which runs from Albany to Cobleskill, passing through the villages of Berne, Gallupville and Schoharie. A branch runs to Middleburgh, though the main line goes through Central Bridge, Howe's Cave to Cobleskill. Another line runs by Thompson's Lake, passing through Delmar, Normansville, Clarksville and East Berne. As this is the first line running through these villages it is expected to be of great service to the business portion of the community.

The Atlantic Coast Telephone Company, which was recently granted permission to run its wires in Atlantic City, N. J., in opposition to the Bell Telephone Company, has completed its organization by electing the following officers: President, E. L. Reinhold; treasurer, Louis Kuehnle; directors: E. L. Reinhold, James B. Reilly, H. Burdcassel, H. L. Heldman, Louis Kuehnle. The company expects to rent 'phones at about $20 per annum. The work of construction will begin shortly.

The Tyson long distance telephone between Savannah, Ga., and Macon is completed, and the line is ready for business. Among some of the towns reached in the trade territory of Savannah are Bloomingdale, Meldrim, Blichton, Arcola, Statesboro, Summit, Graymont, Hillburn, Dardenville, Swainesboro, Stillmore, Covena, Rentz, Rixville, Crooked Run, Lothair, Mt. Vernon, Adrian, Odomville, Ethel, Kite, Wadley, Bartow, Louisville, Dublin, Spring Haden, Dexter, Jeffersonville, Danville, Wrightsville, Lovett, Kennell and Sandersville.

A San Francisco dispatch states that it is reported there that a contract for laying a cable between the United States, Hawaii, the Ladrones and the Philippines has been let and that communication over it will be possible within a few months. Most of the surveys have been made except some soundings between Hawaii and the Ladrones.

The Columbia (Pa.) Telephone Company at its annual meeting elected the following officers and directors: President and general manager, H. O. Young; secretary Frank G. Paine; treasurer, H. F. Yergey; superintendent, Harry W. Johnson; directors: M. R. Hoffman, H. F. Yergey, A. W. Geiskie, Charles Rochow, Joseph Loder, Frank G. Paine and Harry C. Young.

At a recent meeting of the city council at Columbus, Ga., an ordinance was introduced and read the first time, the effect of which will be, if passed, to give a telephone franchise in Columbus to E. W. Coleman. Mr. Coleman is a North Georgian, who proposes to put in an independent system at Columbus in opposition to the present system of the Southern Bell Telephone Company.

The equipment and franchises of the East Tennessee Telephone Company, located in Knoxville and East Tennessee, have been mortgaged to the Nashville Trust Company. The mortgage is for $150,000. It is not known to outsiders to what use the company proposes to put the money.

The Paterson, Passaic & Suburban Telephone Company, a rival of the New Jersey & New York Telephone Company, has started preliminary work in Passaic and promise to have several miles of subways completed in that city before the end of the year.

The Mutual Telephone Company of Des Moines, Ia., has made a contract with the Sterling Electric Company of Chicago for a new switchboard which will have a capacity for 2,000 subscribers.

Dowagiac capitalists will establish a new telephone system at Niles, Mich., to compete with the Bell company. The system will be first class in every respect and will be connected with the independent long distance line.

There are four applicants for franchises in Perioa, Ill.—the Central Union Telephone Company, the Fulton County Telephone, the Automatic Telephone Exchange Company and another.

A local telephone company is to be organized at New Richmond, Wis., at once, and it is expected that about seventy-five phones can be put in.

A franchise to erect and operate a District Messenger service, Fire and Police Telegraph, at Dallas, Tex., has been granted to O. J. Gorman and associates of that city.

New Companies Incorporated.

The People's Telephone Company, London, Ont. Capital stock, $100,000.

The Rivesville & Montana Telephone Company, Fairmont, W. Va.—to construct and operate a telephone line from Fairmont to Rivesville. Capital stock, $50,000. Incorporators: C. E. Gaskill, F. B. Clayton, J. P. Coogle and others.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 11@11⅛c.; Lake, 11⅛c.; casting, 11@11⅛c.

The earnings of the Halifax (N. S.) Electric Tramway amount to about $14,000 a month. The capital stock of the company is $800,000.

The Chicago Edison Company has sold $350,000 new 5 per cent. gold bonds on a 4½ per cent. basis, making $3,325,000 of this issue now floating.

The Erie Telephone & Telegraph Company has declared its regular dividend of 1 per cent., payable August 15. Books close August 6 and reopen August 15.

The trustees of the Street Railway & Illuminating Properties declared a dividend of $4 a share on the common stock, payable July 30.

The New England Telephone & Telegraph Company has declared a regular quarterly dividend of $1.50, payable August 15. Books close August 1 to August 13 inclusive.

On August 11 stockholders of the Commercial Cable Company will hold a special meeting for the purpose of voting on an increase in the capital stock of $400,000.

The Albany (N. Y.) Construction Company, the corporation which is to build the Albany, Helderberg & Schoharie Railroad, has filed in the county clerk's office at Albany a certificate of the payment of its capital stock, amounting to $5,000.

The Western Union Telegraph Company's central cable office, New York, reports that hereafter (change began August 1) the rate to Bermuda will be 42 cents per word, instead of 81 cents, the former rate.

On the 26th ult. the committee on railroads of the St. Louis city council reported with numerous amendments the bill for a consolidation of the Lindell Railway lines. The bill as amended gives the Lindell Company the right to build eleven miles of new track.

The Detroit, Plymouth & Northville Electric Railway Company filed a mortgage at Detroit, Mich., on the 26th ult. for $150,000, running to the Union Trust Company. The mortgage is on the franchises and real estate of the company, and is to secure an issue of $125,000 worth of bonds.

It is reported on what is stated to be good authority that leading interests in the Pennsylvania Railroad Company have become large stockholders in trolley companies in cities and towns through which the Pennsylvania runs. This is thought to be preliminary to a possible control of the trolley lines for the sake of the steam roads.

The United Traction Company of Pittsburg, Pa., makes the following statement for the year ending June 30: Gross earnings, $1,475,764; expenses, $685,819; net earnings, $789,944; fixed charges, $590,445; balance, $199,499. The preferred dividend calls for $150,000, so that $49,000 is left for the common stock, of which there is $17,000,000.

A certificate of an increase of the capital stock of the Nassau Railroad Company of Brooklyn from $6,000,000 to $15,000,000 was filed at Albany on the 28th ult. with the Secretary of State, the increase having previously been approved by the State Railroad Commission. The increase is to be expended in pay for road extensions and improvements already made and to be made.

The Anglo-American Telegraph Company announces an interim dividend for the quarter ended June 30 of 15s. per cent. on the ordinary stock and £1 10s. on the preferred stock, after placing £6,000 to renewal fund. A year ago, after the same sum had been transferred to renewal fund, the dividends were respectively 14s. and £1 8s.; £17,580 is carried forward, compared with £8,500.

The Philadelphia "Times" of July 28 says: "Some of the interests in the American Railway Light Company are understood to consider it the best course for the company to go into the hands of a receiver and reorganize. The opinion is expressed that as there is no money in the treasury and $2,500,000 stock outstanding, all of the treasury stock having been sold, the company should be rehabilitated, as it is claimed the patents and system are valuable."

The Boston "Commercial Bulletin" of Saturday last says: "Directors of the Boston Elevated Railroad Company declared a dividend of 2½ per cent. on Thursday, payable August 15 to stock of record August 1. This is on the $50 per share paid in. Insiders prefer to have it understood that the foregoing is not a dividend, but interest on the amount paid in for six and one-half to seven months, ending August 1. The money represents income from various sources."

When questioned on the subject of the consolidation of the Chicago street railways, which it was reported Mr. Leiter had brought about, President Charles T. Yerkes of the North and West Chicago street railroad companies, said: "The article in a morning paper stating that I have a scheme to consolidate all the street railroads of Chicago, and that I went to New York to meet Mr. Leiter and talk the matter over with him, was absolutely without foundation. I have had no meeting or conversation with Mr. Leiter while in New York, or ever, on the subject of consolidating the street railways."

The Porto Rico Commercial Company filed articles of incorporation at Trenton, N. J., on the 28th ult. The company is authorized to do a general shipping and commission business, build docks, piers, wharves, own and use steamers and sailing vessels for carrying freight or mail, build and operate telephone or telegraph lines, own and operate electric railways, and construct and operate grain and other elevators, flour mills and sugar refineries. The capital stock is $500,000, divided into 5,000 shares, of which William D. Martin, of New York, holds 1; Felix B. Ruthenburg, of New York, 4; Isaac W. Taussig, of New York, 4, and Allen W. McDermott, of Jersey City, 1.

According to the so-called Ackerman report on Chicago street railways, street railway traffic in that city has increased 105 per cent. in ten years. This increase was greatest on the south side, where it reached 118 per cent. The west side increase was 100 per cent. and the north side 87 per cent. A good reduction in operating expenses is shown in the ten years. In 1888 the Chicago City Railway's operating expenses were 73 per cent. of gross earnings, last year 60.40 per cent. West Chicago's in 1888 were 65 per cent., last year 49.50 per cent. North Chicago's in 1888 60 per cent., last year 46.83 per cent. In 1888 a fair proportion of the city's mileage was covered with horse power which now is operated by cable and electricity.

"Bradstreet's" says: "Perhaps the most convincing proof of the truth of the saying that 'trade follows the flag' is found in the quick recognition given by American business men to the possibilities lying practically dormant in the territories recently opened to American enterprise by American sailors and soldiers. However disinterested our motives for interference in Spain's dependencies may have been, there is no escaping from the fact that with the triumph of American arms has come a healthy inclination on the part of American business interests to explore and exploit the resources of the sections of country now under American rule."

The Boston "News Bureau" says: "A. B. Ryan, president, W. R. Usher, treasurer, and A. P. Sawyer, director, of the Electrolytic Marine Salts Company, issue a statement to stockholders, in which they say that the story in the New York 'Sunday Herald' is conclusive evidence of a conspiracy on the part of Messrs. Jernegan and Fisher, that they have undoubtedly left the country and disabled the electrical apparatus at North Lubec. Active measures have been taken to apprehend the criminals and protect the stockholders, and a call for a stockholders' meeting will soon be issued."

ELECTRICITY.

Vol. XV. NEW YORK, AUGUST 10, 1898. No. 5.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4081 Cortlandt.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	2.00
FOREIGN COUNTRIES,	4.50
SINGLE COPIES,	10 cents

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY

THE AMERICAN NEWS COMPANY.

EDITORIAL NOTES.

Education as a Promoter of Commercial Interests.

The United States during the last few years has made marked progress in the matter of finding new foreign markets for its products, as may readily be gathered from the fact that in 1897 our exports amounted to $1,050,993,556, as against $1,231,329,950 for the fiscal year ending in 1898; an increase of $180,336,394 in spite of the more or less unsettled condition of the country. The manufacturers of this country, and especially those in the electrical and kindred lines, are apt to forget however that the desirable fields for American products and manufactures, such as for instance Japan, China and South America, present equally attractive markets for those of other countries. This contest promises to be one of long duration, governed solely by the survival of the fittest. Just to whom the honor of supplying the numerous markets that are slowly being created will belong is difficult to predict, but it is inevitable that it will be that country whose men are best fitted to cope with existing conditions in other countries, who speak the language of those countries, and who are in every way up to date. That these conditions are recognized in other countries is a well-established fact, and as an evidence of this we find Germany, our most formidable rival in the manufacture of electrical apparatus, starting commercial schools for the purpose of equipping her young men thoroughly for these ends.

Austria-Hungary will on the first of next October open an institution in Vienna to be known as an "Export Academy." This is the outcome of a suggestion offered last year by Emperor Francis Joseph, to the effect that every effort should be made to encourage the export of home industries, and that to attain that end it would be necessary to give the coming members of the industrial communities a special education in commercial matters in order that they should be fitted in every respect to become the developers of home trade with foreign countries, and that they might be able to fill the position of Consul in those countries with a reasonable degree of intelligence and consequent success.

The institution in Austria has received the sanction and financial support of the home Government. This move is a practical one. Our own exports show an increase for the past fiscal year that has been phenomenal, but the men who are to-day at the head of our large manufacturing concerns, and who have grown up with the increase of trade and are thus in a measure fitted to cope with the situation without a special training, cannot last forever, and then will come the need of young men acquainted with foreign languages, customs laws and transportation facilities—in short, men of sufficient education to leave them masters of the situation in every instance that may arise. Then again, our consular service almost invariably undergoes changes with every passing Administration, and in many instances men are chosen for their political rather than their commercial ability; the result is that oftentimes men are assigned to positions the requirements of which they are wholly unacquainted with and to whom in many cases the language of the country is unknown. Is it reasonable to suppose that such a man could exert as much influence as could a man thoroughly equipped beforehand for the work? No matter how willing or how patriotic he may be, he is handicapped, and this too at a time when other countries are bending every effort to the advancement of their interests in all the foreign markets of the world. To keep pace with other exporting nations it behooves us to push steadily on, organize, equip and provide export educational institutions, and in this way, together with a careful study of the tastes of all prospective customers and a ready compliance with their wishes, our foreign trade must necessarily expand far in advance of our present expectations or the conceptions of even the most sanguine.

Device for Preventing Collisions at Sea.

Elsewhere in this issue will be found an illustrated article which describes in detail an ingenious device invented by Mr. Hermann Herberts for the purpose of warning a vessel at sea during a fog of the approach of another vessel, or of the vicinity of an iceberg, and thus reduce to a minimum the chance of another such accident occurring as was recently met with by the ill-fated La Bourgogne. Various types of auricular signals have been in use for some time in conjunction with the eophone, topophone and other similar receiving devices with varying success. Mr. Herbert's device however is based on the principle that an object emits heat radiations when its temperature is either higher or lower than the surrounding atmosphere. By a novel arrangement of a thermopile to receive such radiations in conjunction with a galvanometer the inventor feels confident he has devised an arrangement that will give warning in time of fog of the approach of a vessel or the proximity of an iceberg or other dangerous object. Two separate sets of apparatus would be required on a vessel, one on each side, and would have to be carefully shielded from outside influences by means of alum or other heat-absorbing solution. The device is very delicate and would not only give warning of the approach of a vessel or

iceberg, but would also indicate its approximate direction. It is unquestionably true that were an apparatus such as the above to achieve what is claimed for it when given a practical trial, it would materially lessen the danger of ocean travel in time of fog and would act as a boon to humanity by preventing such frightful catastrophes as that of La Bourgogne.

The "Electrical World" and Electrical Fakes. In reference to the Electrolytic Marine Salts Company's bubble, which has just broken so disastrously for many New Englanders of moderate means, we are pleased to see that some of our electrical contemporaries have taken the matter up and aptly point to the evil effect such swindles have upon the electrical industry in general. For instance, the *Electrical World* in an editorial of August 6 on the above subject says: "The majority of these fraudulent schemes are self-evident, such as, for example, the power-multiplying device recently exploited and actually exhibited. Against such it seems that not only the technical press, but those engaged in any branch of the industry, should wage unceasing war. *They should be exposed before the harm is done, not afterward.* There is no public service that can be rendered by the members of the electrical fraternity greater than the stamping out of the charlatans who bring it into disrepute and the swindlers who use the legitimate triumphs of science to mislead and rob the public. The public cannot protect itself from these thieves, because it does not know how; those of us who do know how can protect not only the public, but ourselves as well, by combining for the exposure and prosecution of all sorts of electrical fakirs."

The italics are ours.

We heartily endorse the sentiments expressed by our contemporary, the *Electrical World*, and have all along felt it our duty to expose electrical frauds *before the harm is done, not afterwards.* But why does the *Electrical World* not live up to its sentiments expressed so grandly? Why wait, as in this case, until the horse is missing and then hurry to slam the barn door with a bang? When the Electrolytic Marine Salts Company was first talked of, ELECTRICITY pointed out, vide its issue of December 1, 1897, that the scheme was a "fake," as what gold there was in solution in the sea could not be procured by any such easy process as was suggested. In our issue of June 8 we further made the statement that the sea water gold scheme should be classed in the same category with the Electropoise, electric combs and electric shoes. Were other electric papers, including the *Electrical World*, as bold and prompt in coming forward at the outset, before much harm is done, and declaring electrical swindling schemes swindles as is ELECTRICITY, fakirs who contemplate using the word "electric" as a bait would think twice before embarking in their projects. This is but one of the many occasions in which ELECTRICITY has proven that it alone has the right to the title of only independent paper in the trade.

Determining Electrically the Speed of Projectiles. It may interest our readers in these war days to know that in determining the speed of a modern projectile electricity plays an important part. The method consists in an ingenious application of the chronograph, which, as is well known, has been used extensively in astronomical work where extreme accuracy is needed and where very small fractions of a second have to be recorded.

The forward velocity of either a bullet or shell after being discharged from a gun is now determined by means of two screens on which a length of copper wire is vertically strung in such a manner as to form a continuous conductor. These two screens are placed in line some fifty yards apart. The wire on the first screen is connected with what is known as a chronometer battery, in circuit with an electro-magnet which holds up one of the chronometer rods, and with a disjunctor, which is an instrument used to break both screen circuits at the same instant. The second screen is then placed in a battery circuit with the disjunotor and the electro-magnet controlling the second chronograph rod.

So long as these two circuits remain intact and an electric current passes through them, the chronograph rods will be held up and away from the chronograph sheet owing to the force exerted by the electro-magnets.

As previously stated, the disjunctor is an instrument which is used to break both circuits at the same time, which is done before an experiment begins with a view to obtaining a point of origin to measure from later. When the circuits are again closed and the chronograph rods consequently lifted, were a bullet to be fired through the screens it would first rupture a wire in the first screen, which would open the circuit and cause the first chronograph rod to drop and register a small wedge-shaped mark on the chronograph sheet. In passing through the second screen the same thing would occur, the second chronograph rod lever being the one to fall this time and register a mark. It is now only necessary to determine the time at which both breaks in the circuits occurred. This is accomplished by accurately measuring the distance between the first dent, the origin and the second dent. By determining by the law of gravity how long it would take a body to fall the distance measured will give the time it took the projectile to travel over the distance separating the two screens. Knowing the length of time it takes a projectile to travel over a given distance, the speed of that projectile per second may readily be computed. An instrument known as the synoronoscope, intended for the measurement of the velocity of projectiles and invented by Lieut. George O. Squier, is on exhibition at the Trans-Mississippi and International Exposition at Omaha.

Under the Searchlight.

Notes and Comments on Various Topics

THE temperature must be exceedingly high in Schenectady to-day!

* * *

HIRAM S. MAXIM, the inventor and manufacturer of rapid-fire guns and many other devices of practical utility, arrived from England on the Etruria on Saturday. Mr. Maxim, besides being an inventor, is something of a wag, and when a press representative tackled him for a talk on his arrival he respectfully declined, saying: "I am the Maxim who works with his hands, but there is another Maxim who talks with his mouth." He however consented to say a few words, closing with the remark: "The last thing my English friends said to me when they knew I was coming to America was: 'Tell 'em not to give up the Philippines.'" Mr. Maxim will stay in New York and vicinity for a few days, and will then go on a visit to his mother who resides in Wayne, Me., and will afterwards spend some time with his wife's relatives in Boston.

* * *

ONE of the New York dailies in describing the recent electrocution which took place at Sing Sing said: "Every man was immovable except the electrician, who threw his lever over again, gave Thorn another shock, which a little later was again repeated." Now we strenuously object to the word "electrician" being applied to an executioner. If a descriptive word is necessary, let it be electrocutioner, but to call a man who should be classed in the same category with an ordinary hangman or with Monsieur de Paris an electrician is an insult to every worker in the electrical field.

* * *

OUR contemporary, the *Electrical Engineer* of London, with its usual conservatism and perspicuity, expresses its opinion of the Electrolytic Marine Salts Company's scheme as follows:

A "Yankee" writing to the *Financial Times* claims that the recovery of gold and silver from the sea can be effected commercially. He says that the Electrolytic Marine Salts Company, which has its plant on the coast of Maine, started operations on February 4 with five machines, which were increased to 114 on March 15, and on May 8 a further increase to 239 was made. Some five million tons of water were manipulated during the period named, and the product for the four months is said to be 940 oz. of gold and 1,814 oz. of silver (worth about £5,000), at a cost of less than £1,000. The second plant of 5,000 machines is now being constructed, and the "Yankee" says "the mine being on the mother lode, there is nó danger of losing the vein." A 3 per cent. dividend has been declared by the company, and yet we prefer to wait another year before believing that the "mother lode" has been commercially attacked.

* * *

THE men in the blockading fleet off Havana are beguiling the weary days by shark fishing on somewhat novel lines. The men fasten a small dynamite cartridge to the end of a wire attached to an electric machine. A lump of pork is attached to the cartridge and thrown overboard, and as soon as the creature swallows the bait the current is turned on, the dynamite explodes, and the shark is blown to pieces.

* * *

THE Philadelphia *Times* says: "It is found that the X-ray shines through a fox terrier as if he were a Chinese paper lantern. The experiment has just been tried on an animal of this species which had swallowed a diamond ring, the trinket appearing twinkling in his midst—visible as a fly in amber or a gold fish in a glass globe. All the dog family will do wisely to lay the lesson to heart and look sharp what they swallow."

* * *

A BOSTON financial paper states that the General Electric Company has secured control of the Schenectady Illuminating Company and the Schenectady Street Railway Company for $750,000. This sum would have paid one half the accumulated dividends on the preferred stock But it is not the policy of this company to pay its stockholders, but rather to capitalize its debts.

* * *

THE Norristown *Herald* is responsible for the following: "Some one says that a man who is struck by lightning cannot swim. He does not want to swim. What he needs in nine cases out of ten after being struck by lightning is a cheap and unostentatious funeral."

Death of Adolph Sutro.

The death of Adolph Sutro at San Francisco on the 8th inst. removes from the busy world a man whose name is widely known not only in this country but abroad, owing to its connection with the great tunnel for drainage purposes which Mr. Sutro constructed at the Comstock lode in Nevada. He was also the inventor of an improved process for the reduction of silver ore. Through his connection with the mining industry he was enabled to accumulate a large fortune, which allowed him to carry out several important enterprises in San Francisco, one of which was the well-known street railway bearing his name. He was one of the early settlers in San Francisco, landing there on November 21, 1850. Although an exceedingly wealthy man he was a strong anti-monopolist and devoted to the interests of the masses. This trait was responsible for his being elected Mayor of San Francisco. He died leaving an estate estimated to be worth between $20,000,000 and $30,000,000. For several years before his death his mind was impaired.

IS THERE ANY EXCUSE FOR COLLISIONS AT SEA?

Means for Detecting the Presence of a Vessel or an Iceberg—How Their Movements May be Followed.

BY HERMANN HERBERTS,
Newark, N. J.

The recent Bourgogne disaster, connected with such heavy loss of life, such fearful dramatic scenes, where brutal selfishness was predominating to such an extent that fiendishly cruel means were resorted to in butchering and annihilating the weaker element, has caused a deep and everlasting impression upon its survivors, upon everybody endowed with a fellow-feeling.

The average person lacks coolness of mind in such critical moments, and in losing all self-control shakes that of those so far unaffected. It seems to me that travelers should be made familiar with the safety appliances on board, and I venture to express the hope that the Bourgogne disaster will not only cause the different navigation companies to give to their patrons practical lessons in using and applying such expedients, but also such further information as may be of benefit to them in case of accidents.

As to the matter of life boats, improvements seem highly desirable and particularly to quick and efficient means for launching them. Many lives were lost just on account of this deficiency. It should be made compulsory for each vessel to have a total carrying capacity of their life boats exceeding by 10 or 20 per cent. the maximum number of passengers carried.

This Bourgogne disaster has stimulated within me the desire of finding some suitable means whereby collisions at sea may be avoided.

Before entering into a discussion of these it may be in order to mention a few methods of signaling now in use. Among the auricular signals we have, with an approximate hearing distance in miles, the following:

Air sirene	10–12 miles.
Steam sirene	8–10 "
Trumpet	6 "
Bell	1 "

This hearing distance is however not constant, and depends upon many conditions which are referred to below.

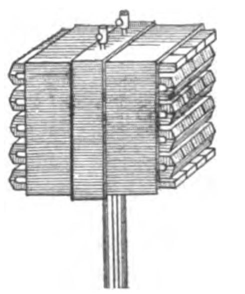
For receiving the sounds the eophone, topophone or similar instruments have been employed with more or less success; the object of these instruments being to furnish a means whereby to determine the direction from which the sound proceeds. The eophone consists of two bell-shaped receivers separated by a central diaphragm, the further end tapering down and being connected with ear tubes. The whole is mounted in a suitable manner whereby it is possible to point the open ends in any direction desired. If the receivers point in the direction of the sound, then each ear will perceive it with the same intensity.

Under existing conditions it is necessary that both vessels be active, not only in giving signals, but also in "attempting" to intercept them. The safety of a vessel consequently not only rests with its own crew, but largely depends upon the watchfulness of the other vessels. A good deal of blind confidence is therefore placed in any stranger who may come along. It is not this alone which makes navigation dangerous during a heavy fog, it is made much more so on account of coinciding circumstances which as yet are not fully understood. At times it is impossible to perceive the phonorous signals when the steamer is nearby, while the signal was plainly heard from some greater distance. As to the cause of this surprising interruption (seeming) in the propagation of sounds, investigations have been carried on by the United States, Germany and France. The investigations made by Major Livermore, in compliance with the United States Admiralty, have thrown some light upon this subject. It has been deduced that obstructions to sound, or an irregular formation of the coast, not only materially affect the strength, but also the propagation of the same. Obstructions behind the source of sound will reinforce them in a similar manner as a screen will reflect the light. Rain and snow will have a great influence upon the direction of the sound.

It has been observed that under certain conditions a sound could not be heard near the surface of the water while it was heard plainly some distance above it. In one experiment Major Livermore's vessel had been placed in such a position that the blowing of whistles, even the shooting of a cannon, was heard at one end of the vessel most distinctly while it was impossible to perceive any sound at the other end, although the steam or smoke could be seen to arise. It seems therefore that under certain conditions sound waves may be projected upward to descend again at some distance and finally take up their original direction. No doubt this remarkable interruption has caused many accidents.

At the first thought it would seem that wireless telegraphy would meet all requirements. Reflecting upon this will soon convince us that each and every vessel afloat would have to be equipped with a complete set of apparatus. Even if their use were made compulsory, the safety of a vessel would be largely dependent upon the other vessels in a similar manner as outlined above.

Although the introduction of this kind of apparatus would make navigation safer, the location and movements of other vessels could nevertheless not



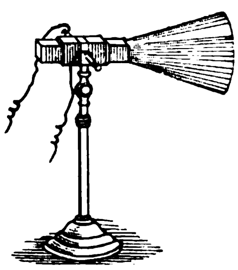


FIG. 1. FIG. 2.

be determined. Besides the vessels there are icebergs and floating wrecks.

Taking all in all it is desirable to find a means which will indicate the nearness or approach of any object.

It is well known that any object, when its temperature is higher or lower than that of the atmosphere surrounding the same, will either send forth heat radiations, or else, in the other case, absorb heat from its surrounding medium. In the winter we clothe ourselves to keep warm; in other words, we surround ourselves with a poor heat conductor so as to diminish the heat radiations from our body to the atmosphere.

If we can construct an apparatus which is acted upon by such heat radiation, and if the apparatus be of such sensitiveness that it will intercept and indicate them, even if they be exceedingly weak, then we have a means which may be advantageously employed in navigation. As soon as we can intercept the radiations sent forth from a vessel we need not depend upon our ear or eye to locate the same.

A modification of the thermopile or the radiophone may be employed in connection with this problem.

A few remarks pertaining to these may prove of interest. Seebeck, in 1822, discovered that an electric current is set up in a closed circuit made up of different metals as long as the junctions would be maintained at different temperatures. The best effects have been subsequently obtained by the use of antimony and bismuth.

Fig. I shows the assembly of suitable metal strips, surrounded by an insulating casing, forming the thermopile. The free ends of the metal strips are connected to binding posts.

Fig. II shows such a thermopile rigidly supported and provided with a conical attachment, which is blackened on its inner surface. It serves the purpose of concentrating the radiations upon the exposed face of contacts, in that way augmenting the effects.

Fig. III shows part of an apparatus as proposed

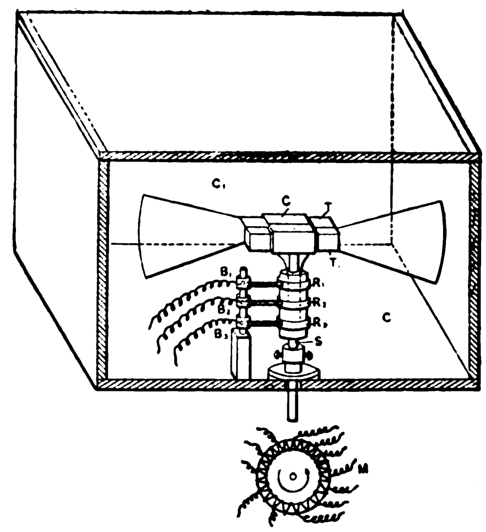

FIG. 3.

by me to the end of detecting the approach or nearness of a vessel, iceberg or obstruction. The two thermopiles T and T_1 are surrounded by an insulating casing C, and are attached to a shaft S, which may be revolved slowly. The insulated rings R_1, R_2, R_3 serve to establish a permanent connection of the thermopiles with the brushes B_1, B_2, B_3 from which wires may be led to the pilot house to the observation or indicating apparatus. The thermopiles are enclosed in a suitable compartment such as to exclude all air currents and to afford protection from the radiations of the sun and the vessel itself.

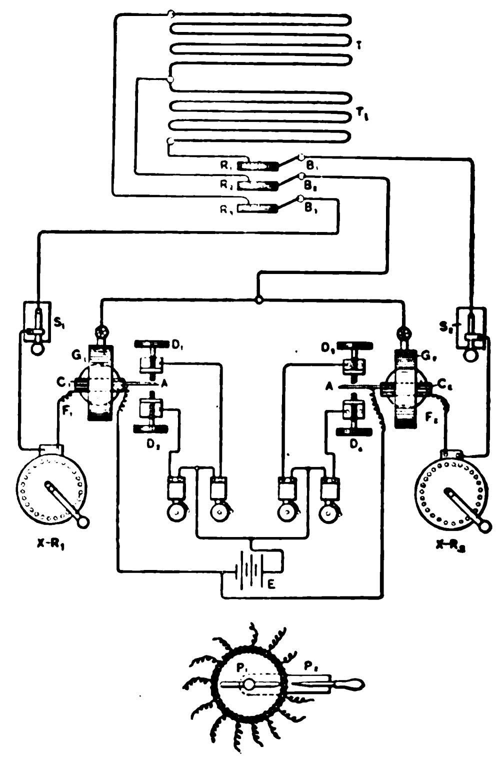

FIG. 4.

For this reason the whole is mounted on the outer side of the vessel. It may therefore be necessary to have one set of apparatus at each side of the vessel to afford a proper protection. A flat ▬ shaped, double-walled casing (not shown) surrounds the compartment C_1; the outer chamber of the former is filled with alum or other heat-absorbing solution for the

purpose of intercepting radiations due to the rays of the sun, either striking directly or being reflected from the water, and also for intercepting those which are emitted from the vessel itself. The inner chamber may be attached to a continuous water supply so as to remove all heat which the alum cell may have absorbed and also to maintain the chamber C_1 at a constant temperature—i. e., the temperature within the chamber should be constantly corresponding to that of the surrounding atmosphere, allowing for radiations just referred to.

Fig. IV shows a diagram of connections. A junction of two of the free ends of the thermopiles T and T_1 is led to the middle ring and thence over the brushes to the two galvanometers, G_1, G_2, here shown of the d'Arsonval type. The other terminals of the galvanometer coil, C_1, C_2, connect through adjustable resistances, XR_1, XR_2, and switches S_1, S_2 to their respective outside rings R_1 and R_2. For observations a galvanometer scale may be employed, or perhaps an automatic indicating apparatus as shown in Fig. IV. A light aluminum arm, A, fastened to the movable galvanometer coil, swings between two adjustable contacts, D_1, D_2, or D_3 and D_4. A local circuit, including batteries E and bells is completed should this arm be turned through a small angle. For indicating the exact position of the thermopile a large number of contrivances may be constructed. In these it should be aimed at to have a position indicator, P, operated by the same current which revolves the thermopiles.

Suppose now that in foggy weather when we cannot see, when we are in fear of being deceived by the sound, we start this apparatus and make ourselves independent of the watchfulness of other vessels. A vessel approaches—we are not aware of it—the radiations given out by the same are too weak to affect the apparatus—we come nearer each other—a stronger current is set up in one of the thermopiles at the moment it points in the direction whence the radiations proceed. Instantaneously the galvanometer coil is slightly turned, the aluminum arm makes contact and causes one of the bells to give a short ring. This happens once at every half revolution, as then the second thermopile becomes active. As the distance between the vessels diminishes, the effect will naturally increase and a contact is made covering a longer period of time. Watching the position of the slowly moving position indicator P at the moment the bell rings, and simultaneously cutting out one of the thermopiles by switch S_1 or S_2, will immediately give us an approximate knowledge of the direction from which the vessel is approaching us. To obtain a more accurate knowledge the adjustable resistance may now be manipulated. It being in circuit with the galvanometer, the current from the thermopile will of course be cut down. Under normal conditions, i. e., with the resistance cut out, the bell will operate for a certain length of time, depending upon the amount of radiations sent forth from the nearing vessel as well as the time of exposure to their influence; this again depends upon the speed of the revolving thermopiles. The purpose of the resistance then is to cut down the action of the thermopile to such extent that the aluminum arm makes contact only at the instant the maximum current is being produced. As this can occur only when the thermopile points directly towards the strange vessel, its position is immediately ascertained by simply moving the contact lever until the bell gives the shortest obtainable ring.

For all ordinary purposes the observation of the slowly moving position indicator arm P will therefore be sufficient. A small adjustable pointer, P_2, which may be swung around the outside casing of the position indicator, may serve to fix this position.

By the increased or diminished action of the thermopiles we know whether a vessel approaches or whether it recedes—by watching the position indicator we know whether the vessel is moving toward the right or toward the left. These means therefore enable us not only to ascertain the presence of a vessel, but also to follow its movements, and all this is accomplished by simply adjusting the rheostat, listening to the bell and watching the position indicator.

Safely passing the vessel, we now come near an iceberg. The effect is similar to that described, the current produced is however now flowing in the opposite direction, causing the coil to turn the opposite way and also a different bell to give its warning signal. It is possible therefore to tell the nature of the obstruction, whether it be a vessel or an iceberg. In the case of a floating wreck more difficulty is to be expected, as its temperature will not differ very much from that of the surrounding atmosphere. It may however be that if its entire exposed surface is in moist condition a sufficient fall of temperature is produced to affect the apparatus, and to do likewise on account of radiations given out due to exposure to the rays of the sun. For the same reasons it may also be possible to tell when nearing a coast.

The double thermopile is proposed for the purpose of increasing the action of the apparatus, as then it is possible to revolve the same at a slower speed, in that way giving a longer exposure to the radiations. At the same time the vessel is better protected. A combination of four of these would undoubtedly improve the effects considerably, as the speed may then be cut down still lower. A plurality of thermopiles suitably arranged would not require to be revolved.

The indicating apparatus, i.e., the galvanometer, should preferably be mounted so as to be free from vibration and in a similar manner to that employed with the compass, to make it independent of the ship's motions.

Now a few remarks touching upon the radiophone.

Berzelius in 1817 discovered selenium; Knox in 1837 found that it was an electrical conductor; May discovered that its conductivity is much influenced by light. In their experiments most physicists used the galvanometer, while Bell used the telephone. Bell and Taintor subsequently constructed the photophone, its receiver consisting of metal disks insulated from each other and covered with selenium. A ray of light—reflected from a mirror diaphragm against which is spoken—after passing through suitable concentrating lenses is reflected to a distant parabolic concave mirror and thence upon a selenium cell, which is in circuit with a telephone receiver and battery. Sound was in this manner transmitted over a beam of light. Later experiments showed that sound can be transmitted more efficiently by non-luminous heat rays. Mercadier then constructed the radiophone. In this instrument soot or lampblack is made use of, forming a bridge between the two electrodes which are in circuit with battery and telephone. For some experiments Graham Bell used a bottle or test tube, covered or filled with soot. Throwing the focused light on these would produce a sound if the rays be of an intermittent nature.

It is a fact, then, that heat rays will affect the conductivity of such radiophonic apparatus. Whether their application to the above end could be accomplished seems at this moment difficult to answer. If their sensitiveness can be brought up to that of the thermopile, and if no serious mechanical difficulties be met with in maintaining the soot in the proper place, then it would become a simple matter to apply such radiophonic apparatus for the purpose stated.

My first conception of applying these means dates back to July 7, 1898. I will not commit myself in stating that such methods as outlined above are absolutely feasible under all conditions, nevertheless they appear worthy of a careful perusal, study and experiment. Certainly a large number of factors must be dealt with in any attempt to solve this problem, so fascinating, interesting, and, what is more, of such vital importance.

The effects of winds, whether warm or cold, moist or dry, blowing toward or away from us and at different intensities; the effects of the Gulf Stream, the absorption of radiations due to the above, rain, snow or fog—all these may require investigation.

On account of the extreme sensitiveness of the thermopile and the galvanometer, I am led to believe that the attainment of the end in view is a possibility.

The need certainly does exist, nor will anyone disprove this statement.

Having means at hand by the employment of which collisions may be avoided, life and property be saved—perhaps your own, dear reader—why then, I ask, "is there any excuse for collisions at sea?"

Seeing all the possibilities, I most heartily advance these rather incomplete ideas and hope that the press here as well as abroad will contribute its share in discussing this subject. I also express the hope that all those interested will not withhold their opinion, and further, that influential parties will lend their aid to bring about a solution of this problem.

POWER DISTRIBUTION IN FACTORIES.*

Although considerable progress has already been made in the introduction of electrical distribution of power in factories, the field is such a large one that what has already been done is really but a drop in the ocean to what still remains. One of the greatest difficulties in the way of the general introduction of electrical power distribution is the want of actual figures, showing the saving effected in factories in which electrical methods have been adopted, as naturally the power user wants to see well authenticated figures and not merely probable estimates of the return he will get for the capital to be expended on an electrical plant. This difficulty is in great measure due to the impossibility of obtaining from the user of power an accurate statement of the average brake horse-power actually supplied to the driving shafts of the machines, or of the pounds of fuel used per brake horse-power-hour. One can learn that there are a certain number of engines in use, each rated at so many horse-power, but in many cases no information can be obtained as to the number of horse-power hours indicated per month or year, nor as to the percentages of the power which are actually applied to the shafts of the machines, or are wasted in engine friction or transmission. On the other hand, although the total bill for fuel and wages of stokers and engine tenders may be given, a considerable portion of this is chargeable in many factories to heating or purposes other than the production of power.

In a paper read before the Institution of Engineers and Shipbuilders in Scotland, Mr. H. A Mavor has given in tabulated form the replies received from a number of manufacturers to inquiries addressed to them by him; and these tables, though interesting as showing the cost per indicated horse-power per hour for fuel, stores and wages, illustrate very well the difficulties named above; as in the majority of cases the information is incomplete owing to no figures being given for the percentage loss in transmission, or to the fact that the proportion of the cost of steam raising which is chargeable to power cannot be determined. The replies received have been divided by Mr. Mavor into two groups, one for weaving, spinning, thread, tweed, corn and flour mills and engineering works, in which power is derived from one or two main engines, and the other for paper mills, chemical, sugar refining and engineering works, in which power is derived from a number of small engines erected in various parts of

*From the *Electrical Review*, London.

the works. From a third table, summarizing the results of the inquiry, we find that for the first group the average coal consumption per indicated horse-power-hour is 3.1 lbs., the average price paid for coal is 5s. 5d. per ton, and the average cost per indicated horse-power-hour for fuel is .091d., for oil and petty stores .011d., and for labor .028d., making a total of .13d. The corresponding figures for the second group are as follows: The average coal consumption is 5.3 lbs., the average price paid for coal is 6s. 4d. per ton, and the average cost per indicated horse-power-hour for fuel is 18d., for oil and petty stores, .01d., and for labor .034d., making a total of .224d. Judging from these average figures the difference between the two groups is not so marked as we should have expected; but this small difference is due in part to the fact that the averages have been calculated from the total horse-power-hours and the total costs of all the factories added together, and as the larger users of power have obtained better results than the smaller users the average figures are proportionately better. If, instead of using this method, we take the coal consumption of each factory, add them together, and then get the average by dividing by the number of factories, we arrive at 10.5 lbs. instead of 5.3 lbs., and we may also note that the heaviest coal consumptions are in engineering works, the actual record figure quoted being for an engineering establishment where the coal consumption amounts to 27.85 lbs. per indicated horse-power-hour, and the cost for fuel, oil and labor to just over five-eighths of a penny. As a further example of the wastefulness of small engines, and of the way in which power users sometimes allow engines to consume steam long after they ought to have been put on the scrap heap, a series of indicator diagrams are reprinted, and the steam consumptions as calculated from them are given as ranging from 53 to 180 lbs. per indicated horse-power-hour, with the additional information that these small engines, which have been in use for about twenty years, are in a factory where the main engines are working with a steam consumption of 14 lbs.

To supplement the information given in the tables referred to above, Mr. Mavor gives particulars of the economical results obtained at a foundry in Glasgow, where 19 small engines were replaced by a gas engine of 120 horse-power, driving a set of hydraulic pumps and a dynamo. The hydraulic gear works lifts, cranes and testing apparatus, whilst the dynamo supplies current to seven motors of various powers for driving cranes and machine tools, and also for lighting a portion of the works formerly lighted by gas and oil lamps. A comparison was made between months, one before and one after the change, in which the output of manufactured product and the work done were the same, and the books show that in the earlier period 566 tons of dross, costing £127, were consumed, whilst in the second period 227 tons of dross and 26 tons of anthracite, costing together £67, were consumed. The net result of the change was therefore a cash saving of £60 per month in cost of fuel, whilst the total saving in working expenses was estimated at from £80 to £100 per month.

Mr. Mavor concludes his paper by some advice as to the best way to effect a change from the old style to the new, so as to show a good return for the capital expenditure from the start. He considers that it is a bad plan to use an old engine to drive a dynamo, or to put down a new engine to take steam from an old low-pressure boiler, and advises that a separate installation of boilers, engines, and dynamos of efficient type should be erected sufficient in the first instance to allow of all the notoriously wasteful isolated engines being replaced by electric motors, whilst leaving untouched any old engines which are working with fair economy, and especially those which are driving groups of machines through shafting. When all the isolated engines have been replaced, and the economy effected by the change is known, the question of how far it will pay to do away with main engines and shaft transmissions and replace them by electrical transmission, can then be safely answered and the change gradually made.

WHAT IS THE HEATING SURFACE OF A STEAM BOILER?*

BY CHARLES WHITING BAKER,
New York City.

It is a fact which is now generally understood by engineers and all who have to do with steam power plants that the power of any boiler, or more accurately the amount of steam which it can furnish in a given time, depends first of all upon its area of heating surface. Of course the amount of steam which a square foot of heating surface will produce varies between very wide limits, and is affected by a multitude of conditions. It is also true that heating surface is no more essential than the means for supplying heat—that is to say, a furnace of sufficient size and grate surface to burn the fuel, and draft sufficient to supply the furnace with the necessary air. The furnace and the chimney, however, are not necessarily parts of the boiler at all; their function is merely to supply the heat, and the function of the boiler proper is to transfer as much as possible of this heat to the water which it contains. Both the amount of heat which it can transfer in a given time and the proportion of the total heat generated which can be transferred vary with the area of the heating surface exposed. In other words, both the capacity and the economy of a steam boiler depend directly upon its area of heating surface.

Evidently, then, the area of the heating surface of a boiler ought to be determined with a fair degree of accuracy. The designer of the boiler must know it, if, with any degree of precision, he is to adapt the boiler to the work which it has to do. The seller of boilers must know it, if he is to be sure of fulfilling his guarantees of capacity or economy; and the purchaser of boilers should know it in order to determine what he is getting for his money. As a matter of fact, a very large proportion of the boilers bought and sold are actually bought and sold by their heating surface. The prices asked for and quoted may be the price per horse-power, but the horse-power is determined directly from the heating surface, the number of square feet allowed to a horse-power varying from 5 to 14, according to the type of the boiler. Again, in comparing the work done by different boilers, the relative heating surface is always taken into consideration.

We need go no further for proof that accurate determination of boiler heating surface is a desirable thing. But we have now to notice the remarkable fact that in computing boiler heating surface, an error of from 7 to 17 per cent. is made by a large proportion of steam engineers and boiler manufacturers. The error to which we refer consists in taking the surface in contact with the water, instead of that exposed to the fire or hot gases, as the heating surface. If the heating surface is flat, of course the areas are the same; but boiler heating surface is in most cases made up of tubes, and the difference between the interior and exterior surface of a boiler tube is as much as 17 per cent. of the interior surface in the case of a 1-inch tube and is about 7 per cent. in a 4-inch tube.

The error arises in the first place from a failure to appreciate the fact that the heating surface exposed to the fire is the actual heating surface of the boiler, on which its capacity depends. A clear understanding of this fact is so important, and it has been and is so generally mistaken by engineers and writers of engineering works, that the writer ventures to submit a discussion of the elementary principles on which this assertion is based.

Suppose we have an iron plate 1 inch thick, on one side of which is flowing a current of hot gas at a temperature of, let us say, 1,000 degrees, and on the other side is a body of water in a steam boiler at a temperature of 300 degrees (corresponding to a gauge pressure of steam of about 52 pounds).

* Paper presented at the Niagara Falls meeting (June, 1898,) of the American Society of Mechanical Engineers.

Now the heat in passing from the hot gas on the side of the plate to the water on the other meets with three different resistances as follows:

(1) Resistance in passing from the gas to the surface of the plate.

(2) Resistance due to the passage through the plate.

(3) Resistance due to the passage from the other surface of the plate to the water.

That one of these resistances which is accurately known is (2), the resistance in the passage through the plate. The heat conductivity of metals has been carefully determined by experiment in physical laboratories, so that if we know the actual temperatures of the two surfaces of a plate and its thickness, we can at once determine how much heat is passing through a unit area in a given time. On the other hand, if we know how much heat is passing through the plate, we can determine what is the difference of temperature of its two surfaces. Let us solve an example of the latter sort: Suppose the plate is transmitting heat enough to evaporate 3 pounds of water per hour from and at 212 degrees per square foot of its area, or about the average rate that the heating surface transmits heat in an ordinary stationary boiler. Since 965.7 heat units are required to transform a pound of water at 212 degrees into steam at the same temperature, the plate will transmit $3 \times 965.7 = 2897.1$ heat units per square foot per hour, or for convenience let us say 2,900 heat units.

Now experiments on the conductivity of metals have shown that an iron plate 1 foot square and 1 inch thick whose opposite surfaces are kept at a uniform difference in temperature of 1 degree Fahr. will transmit in an hour 473 British thermal units.*

Hence to transmit 2,900 British thermal units per hour, the difference in temperature of the two sides of the plate will be $2,900 \div 473 = 6.13$ degrees.

I doubt not it will surprise many to learn that so small a difference of temperature between the two surfaces of an iron plate is sufficient to cause so large an amount of heat to flow through it; but the coefficient for the heat conductivity of iron on which it is based is the result of many experiments by the most eminent physicists, and is accepted as correct by the best scientific authorities, and there is no reason to doubt its accuracy.†

In studying our present problem, however, the exact accuracy of the coefficient is a matter of no particular importance. We just found that boiler heating surface 1 inch thick, when transmitting 2,900 heat units per hour, will have a difference of temperature on its two sides of 6.13 degrees Fahr. But we never have heating surface of such thickness in steam boilers. The shell heating surface in internally fired boilers is seldom over $\frac{5}{8}$-inch thick. Furnaces and fire boxes are made of $\frac{1}{4}$-inch to $\frac{3}{8}$-inch plates, while tube heating surface is from $\frac{1}{16}$ to $\frac{1}{8}$-inch thick. We see then that the actual difference of temperature between the two surfaces of a boiler tube transmitting heat at the rate already named will be from $\frac{1}{8}$ to $\frac{1}{16}$ of 6.13 degrees, or in round numbers from $\frac{3}{8}$ degree to less than 1 degree Fahr. As the eminent physicist Lord Kelvin has said, for all practical purposes we may consider that the heating surfaces of steam boilers conduct heat as if they were no thicker than paper, or as if the metal were of infinite conductivity. It will be seen also that an error of 50 per cent., or even of several hundred per cent., in determining the coefficient of conductivity of iron, even if such an error were probable, would make no practical difference in this conclusion.

There are many facts of practical importance to be drawn from this. For example, in its light we can readily see how little reason there is to expect any greater economy in locomotive boilers with brass

*See Ganot's "Physics," 13th ed., page 378.
†Many engineering text-books and pocket-books still quote Rankine's formula and Peclet's coefficients for heat conductivity; but the latter have been found by the more careful research of modern physicists to have been largely in error.

or copper tubes and fire-boxes than in those of steel. Yet we still hear the superior conductivity of copper urged as a reason why English railways stick to the use of copper fire-boxes.

We know now that the two surfaces of the plate, previously referred to (if we conceive its thickness reduced to that of an ordinary boiler tube), will have only a trifling difference of temperature. Next let us discuss the relative heat-absorbing powers of the water on the one side of the plate and the hot gases on the other. It is to be kept clearly in mind that the temperatures of the two sides of the plate which we have just considered are the temperatures of the skin of the plate itself, which is quite a different matter from the temperature of the air or the water in contact with the plate.

If this is clearly understood, it will be easy to understand that the actual temperature of the plate itself depends on the relative heat-transmitting power of the fluids on its two sides. If these fluids were the same on the two sides, and were at the same temperature and under the same conditions as respects mobility, then the plate temperature would be a mean of the temperatures of the fluids on its two sides. But since water is many times as efficient as air or furnace gases in absorbing heat, the plate temperature will be nearly the same as that of the water and far below the temperature of the hot gases.

This is a fact which is a matter of common knowledge, and yet it has been overlooked by many engineers and by engineering writers; and because it has been overlooked is one main reason why engineers have not always insisted on the fire side of tubes being considered the heating surface of steam boilers.

Let us review some of the facts which show the relative heat-absorbing power of the water and gases. Take an iron rod and heat it to redness, then let it be held still with only the air in contact with it, and see how long a time elapses before it is cool enough to be touched. Heat the rod to redness again and then plunge it in water and again note the time before it can be touched. We have then a very rough approximation of the relative heat-absorbing powers of air and water.

Again, experiments have been conducted to determine the temperature to which a metal plate could be heated when one side was in contact with water. The temperature was determined by inserting in it plugs of various fusible alloys, and the fire side of the plate was then subjected to the most intense heat that a powerful blow-pipe could produce. So long as the water side of the plate was clean, it was impossible to melt the fusible plugs.*

The most striking illustration, however, which the writer has ever seen of the large heat-absorbing power of water, as compared with air, was an experiment conducted by him for another purpose some years ago. A vessel having a single vertical tube of about 2 inches diameter was filled with cold water (45 degrees to 50 degrees Fahr.); the hot gases from a large oil lamp or a Bunsen burner at a temperature of some 1,000 degrees or more were then passed up through the tube. The surface of the tube exposed to the hot gases was kept so cold by water on the other side that drops of dew were condensed upon it from the hot gases, and the interior of the tube became actually coated with dew, which remained until the water was warmed to about 60 degrees. I advise anyone who may not be convinced as to the enormous heat-absorbing power of water as compared with gases to try this simple experiment.

It is very easy to understand why water should have so much greater heat-absorbing power than air. The specific heats of water and air are as 1 to 0.23 for equal weights; but since air at ordinary temperatures weighs only $\frac{1}{812}$ as much as an equal volume of water, if we consider a thin film of air in contact with a hot surface and a film of water of equal thickness and area in contact with a similar hot surface, the water would absorb 3,530 times as much heat as the air if the temperatures of each were raised an equal amount. Again, the relative heat conductivities of water and of air, according to Lord Kelvin, are as 40 to 1. On the other hand, in the transmission of heat from a surface to a fluid, the mobility among the particles of the fluid, whereby fresh portions of it are constantly brought in contact with the surface, is a matter of great importance, and in this respect air, of course, has a considerable advantage.

The writer has been unable to find any trustworthy figures for the relative heat-absorbing power of air and water; and the practical importance of their accurate determination would be trifling, for we know in a general way and from the examples already cited that water absorbs heat very many times more rapidly than air, so many times that in the case of a thin plate, such as a boiler tube, transmitting heat from furnace gases on the one side to water on the other, we can be quite certain that the temperature of the metal plate is at most only a few degrees warmer than the water in contact with it.

In other words, in any steam boiler with clean heating surfaces we can assume the temperature of the fire side of the heating surface to be practically the same as that of the water in the boiler. Perhaps it may be 1 degree more; perhaps it may in some cases be 20 degrees, or possibly 30 degrees more. The difference is of no practical importance, since in the few cases where so large a difference as 20 degrees or 30 degrees may possibly exist, the temperature of the fire to which the surface is exposed is greater by probably 2,000 degrees or more than the temperature of the plate.

If, now, it is clear that the fire side of the boiler tube or flue is at practically the same temperature as that of the water in the boiler, the reader will have little difficulty in comprehending that this surface, and not the surface on the water side, is the real heating surface of the boiler, which measures its capacity of making steam.

The great resistance to the flow of heat in any steam boiler is in getting the heat from the hot gases into the surface exposed to them. Compared with this, the resistance to the passage through the plate and the resistance to the passage from the plate into the water are mere trifles. If we increase the surface exposed to the hot gases, we shall increase the capacity of the boiler to absorb heat; but if we leave this surface the same and increase the surface exposed to the water, the amount of heat transmitted in a given time will be practically the same.

The case can be made still more clear perhaps by an analogy to the flow of water through pipes. If we have a length of 1-inch pipe connected to two lengths of 12-inch pipe, and allow water to flow through them under a head, it is clear that the flow will be determined by the resistance of the 1-inch pipe. If we enlarge that, we shall enlarge the flow; but if we leave that alone and enlarge either or both the 12-inch pipes, the flow will be practically unchanged.

The area of the fire side of the tube is what determines the heat absorbing power and the steam-making capacity of the boiler. If we can cause this to take up more heat in any way, we shall increase the power of the boiler. The Serve tube, with its ribs extending into the hot gases, increases the interior surface of the tube, and thus its capacity for absorbing heat. If, however, instead of putting ribs on the fire side of the tube, we put them on the water side, we increase the surface exposed to the water, but we make no increase of any practical importance in the amount of heat transmitted. In a similar way, the curved form of the tube, which causes the surface exposed to the water to be greater than that exposed to the fire (in fire-tube boilers), effects no increase in the amount of heat transmitted. The real heating surface, which determines the amount of heat transmitted, is the surface exposed to the fire.

In the preceding discussion it has been supposed that the heating surfaces were clean on both sides. As a matter of fact, heating surface is almost invariably more or less coated with soot or ash on the fire side and with scale on the water side. If the preceding discussion has been carefully followed, it will be clear that the transfer of heat will be much more interfered with by the deposits on the fire side than by deposits on the water side. To use again the analogy of the water pipes, a half-closed valve in the 1-inch pipe would have far more effect than a half-closed valve in the 12-inch pipe. It is no part of the purpose of this paper to excuse lack of care in keeping boilers free from scale; but it is nevertheless quite certain that a thin scale on boiler tubes does not interfere in any noticeable degree with the capacity or economy of a boiler, while the coating of the fire side of the tubes with a flocculent deposit of soot does certainly interfere in a marked degree with a boiler's steam-making capacity. Of course, a thick scale on the water side of tubes or other heating surface, or any other material which acts as a non-conductor, may considerably obstruct the flow of heat. If it does this, the temperature of the heating surface itself will at once be raised, and may reach a point, as happens sometimes with the shells of externally fired boilers and with the furnaces of marine boilers, where the metal may be so heated as to bulge or buckle.

It may be worth while in this connection to administer a puncture to that hoary fraud which has been repeated in technical literature and trade catalogues "ad nauseam." I refer to a table purporting to give the loss of economy in percents for each one-sixteenth-inch of scale upon the heating surface of a boiler. In view of the fact that there are many varieties of boiler scale, varying widely in porosity and heat conductivity, and remembering that the thickness of scale in different parts of a boiler is never uniform, it hardly needs the discussion above to show the utter absurdity of this ancient "fake."

Another deduction of practical importance from the fact just set down, is that so far as the transmission of heat after the boiler is making steam is concerned, the circulation of the water in boilers is of a good deal less consequence than has been sometimes claimed. I do not mean by this that it is not worth while to make proper provision for circulation. There are possibly some parts of boilers worked with forced draft, such as the tube-plates of marine boilers, where it is so difficult for the steam bubbles to get away fast enough that we have a mass of foam instead of water in contact with the plate. Under such conditions, of course, the plate is bound to be heated; but I know of no evidence that this is any other than a rare occurrence, even in boilers which are pushed most severely. If anyone is inclined to stick to the old hobby that circulation is of great importance to economy, I advise him to consider the conditions in the narrow water space (about 3½ inches wide) around a locomotive fire box, where the steam rushing up is directly opposed by the water going down. Let it be understood that I am referring to circulation only as affecting the transfer of heat and the consequent economy and capacity of the boiler. Good circulation is desirable to prevent unequal heating of the boiler, and consequent straining, and it may be of service in preventing deposits of scale and mud in places where they are least desirable; but that it has any appreciable effect on economy and capacity is not proved, and probably cannot be.

---

* It may be well to point out that this method of determining the maximum temperature reached by the plate is subject to more or less error on account of the obstruction to the passage of heat from the plug to the metal of the plate (the plug being merely embedded in the surface of the plate and not passing entirely through it). Any joint between two metal surfaces interferes with heat conductivity just as it does with electrical conductivity. The amount of interference depends upon how intimate the contact is between the metals, the amount of oxides (if any) between them, etc.

It has been demonstrated above that the surface exposed to the fire is the real heating surface of a steam boiler. Is there any good reason why this should not be generally adopted by engineers as the correct, and the only correct, method of computing heating surface?

The following are some reasons, good or bad, which are likely to be urged against this:

1. The makers of fire-tube boilers will claim that this gives the water-tube boiler makers an advantage. With the same number of tubes in a boiler, of the same length, the water-tube boilers can show 7 to 11 per cent. greater heating surface. This is of course true; but is it not an advantage to which the water-tube boilers are fairly entitled? It must be remembered that nowhere in this discussion has it been claimed that there was any fixed heat transmitting value for heating surface. On the contrary, it is entirely certain that a square foot of heating surface in one type of boiler may have double the heat transmitting power of an equal area in another. Again, the relative facility with which heating surface can be cleaned of soot and ash counts for a vast deal, more than most steam users are accustomed to think. It certainly seems that the makers of fire-tube boilers have enough valid arguments to offer for their product without demanding the privilege of overstating their heating surface by 7 to 11 per cent.

2. Another argument offered for the use of the exterior surface as the heating surface is that this makes a given boiler show a larger heating surface than if the interior were taken. However much the argument may appeal to boiler manufacturers—and I hardly think they will take it very seriously—it deserves no weight with engineers. A foot rule is no longer for calling it 13 inches.

3. It is urged that practice is and has in the past been fairly uniform in accepting exterior area as the heating surface, and it is best to stick to a uniform practice, even if it be in error, than to change. If the practice were actually uniform, there might be reason in this argument; but while the majority of engineers probably use the exterior surface of tubes in computing heating surface, there is a very respectable minority which insists on the correct method of computation, and this minority shows no signs of decreasing.

4. As the outside diameter of the tube is even inches and the thickness of tubes varies, it is easier to compute the exterior heating surface than the interior. Probably this is one of the principal reasons why the outside surface has so frequently been taken; but in these days of tables and pocket-books and aids to computations, so trifling a matter as computing the interior area of a tube ought not to be an excuse for perpetuating an error. As a matter of fact, it will generally be less labor to do this than it is to figure the cost of the tubes with the numerous series of discounts which are frequently found on hardware bills in these days.

It appears to the writer that none of the arguments which have been cited in favor of computing the exterior surface of tubes as their heating surface are sound enough to justify engineers in perpetuating this error. If, however, for the sake of uniformity or ease of calculation, it should be thought best to use the exterior surface of tubes in computing heating surface, the fact that this is not the real heating surface ought to be kept clearly in mind. Misconception and wrong ideas on this point have been responsible for not a few mistakes and absurdities in the design of steam boilers.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

ALUMINUM MANUFACTURE, WITH DESCRIPTION OF THE ROLLING-MILLS AND FOUNDRY AT MILTON, STAFFORDSHIRE.*

BY E. RISTORI.

On the occasion of the meeting of the Institution of Mechanical Engineers at Belfast in July, 1896, Mr. James Sutherland, the manager of the factory at Larne, read a paper which fully described the method adopted for the preparation of pure alumina (oxide of aluminum) from bauxite. Members who then visited the factory will be interested to learn that the British Aluminium Company have already been compelled to enlarge the works to nearly double the capacity, and that great improvements have since been introduced into the process of manufacture. The finished product is a very finely divided powder, and in order to ship it safely to Foyers, it has been found advisable to pack the alumina in hermetically-sealed steel drums. On arrival in Scotland, the oxide is reduced by the Héroult process, and the metal is run out of the electrolytic baths into ingot molds. In this form the aluminum is quite pure enough for certain purposes, such as foundry work and steel making; and much of it is therefore sold without further treatment. But as small quantities of the cryolite—a double fluoride of aluminum and sodium containing 13 per cent. of aluminum—which is used as a solvent during the electrolysis, occasionally become mixed with the metal as it comes out of the furnace, the aluminum at this stage is scarcely suitable for the production of tubes, rods, etc. The original crude ingots are, therefore, sent to Milton, in Staffordshire, where they are remelted and refined until the metal attains a purity of 99.6 per cent.

Milton Works.—The site of the Milton Works, which the members will have an opportunity of visiting, is well selected in the middle of an industrial district; it is connected with the North Staffordshire Railway by a siding, and has a frontage on the Trent and Mersey Canal. The works were the first erected in the United Kingdom for the production of aluminum by electrical agency. They were erected by the Cowles Syndicate for the purpose of turning out aluminum and aluminum bronze by the well-known "Cowles" process; but before the British Aluminium Company took them over they had already stopped making aluminum, having been previously driven out of the field by the competition of the electrolytic methods, which were greatly assisted by the employment of cheap water power. It was found useful, however, to convert this factory into a rolling-mill and foundry, with the idea not only of refining the Foyers ingots, but also of working them up into sheets, rods, and large or small castings, more convenient for the different trades that use aluminum. A portion of these works which was not required for the above purpose was sublet to the Epstein Electric Accumulator Company, who have been making and charging their accumulators here for the last three years. This portion includes two tubular boilers and one engine of 650 IHP.

Casting-Shop.—The casting-shop, erected in 1895, is situated close to the rolling-mills, and contains a series of 11 furnaces for 500 lb. pots, connected by a large flue to the main chimney, 125 ft. high, which gives a good draught for melting large quantities of bronze in a short time. This shop can deal with about 40 tons of aluminum per day in the shape of ordinary commercial notched bar, half-round stick for steelmakers, slabs for rolling, tube billets for drawing, wire billets, both round and shaped, for various purposes. When casting the metal it is sometimes necessary to add a little cryolite or some similar flux for assisting in the liberation of the impurities, which then rise to the surface as scum. These refining furnaces are fired with soft coke, because aluminum does not require such a high temperature as is necessary for bronze. The scum taken from the top of the pots is again remelted very slowly, in order to recover all the aluminum; it then forms a whitish powder, containing practically nothing but the cryolite and some carbon, and being quite suitable for use in the Héroult reducing cell is sent back to Foyers for further employment. An overhead traveling crane is used for lifting the ingot molds and pots. Experiments have been made in casting slabs and billets with a side runner, which seems to offer certain advantages.

Foundry.—The principal building, which was originally intended by the Cowles Syndicate to be an engine and dynamo house with outside boilers, is 200 ft. long by 65 ft. wide and 20 ft. high under the principals. A portion of this is now used as a foundry, and contains two large core ovens, each 16 ft. by 23 ft., having a door 14 ft. by 10 ft. high, fired with coke fires under the floor; a cupola; two series of crucible furnaces to hold 500 lb. pots; and two traveling cranes, sufficient to handle weights up to 15 tons, which so far have been sufficient for all the foundry work up to bronze castings of five tons weight and aluminum castings of two tons. A considerable extension of the plant is contemplated. In making bronze castings the metal is not poured straight into the mold in the usual way of casting iron, but into a runner box, or for a large casting into a number of runner boxes, having holes in the bottom corresponding with the gates of the casting. During the time the metal is being poured into the runner box these holes are filled with iron plugs until all the metal is in the runner box; the plugs are then taken from the holes, so that the metal runs into the gates of the casting from the bottom of the runner box, and leaves the scum behind in the box or in the top of the gates. In making castings of aluminum, it is not sufficient to use runners of the same size as those usually employed in making brass and iron castings. As the shrinkage of aluminum is about three times the shrinkage of ordinary gun metal, a considerable amount of trouble is experienced if the runners and risers are not large enough to allow the casting to continue to be fed during its shrinking by the runners or risers connected with it.

Rolling-Shop.—The rolling-shop measures 130 ft. by 60 ft., and is covered with a weaving-shed roof having a north light. At present it contains two pairs of rolls 18 in. diameter by 42 in. width, one pair 18 in. diameter by 48 in. width, one pair 18 in. diameter by 20 in. width, one pair 14 in. diameter by 20 in. width, one pair 14 in. diameter by 30 in. width, and a new pair of friction rolls 22 in. diameter and 60 in. wide is in process of erection. All are driven by gearing from a horizontal tandem compound-condensing engine, put up in 1896. This engine runs at 60 revolutions per minute, and has cylinders of 21 in. and 40 in. diameter and 40 in. stroke, and is capable of driving still more machinery. The steam is supplied by a Lancashire boiler 8½ ft. diameter and 30 ft. long, placed at the side of the house. The driving gear consists of helical-tooth wheels, 12 in. wide and from 6 ft. to 9 ft. diameter, driving the rolls at about 10 revolutions per minute. The 14 in. rolls are both fitted with a friction wind by Messrs. Jones, of Birmingham, with which strips as fine as 0.0005 in. have been successfully rolled to a length of from 69 ft. to 90 ft. The rest of the plant required in a rolling-mill is also contained in this building. It includes a guillotine shearing machine for ½ in. plates, 8½ ft. wide, a crocodile machine for plates up to 1 in. thick, two circular cutters, one for the manufacture of disk blanks 9 in. to 24 in. diameter up to 14 S.W.G., or 0.085 in. thick, the second up to 4 ft. diameter and ⅛ thick, which are sold for stamping purposes; a steam-

* Paper read before the Institution of Mechanical Engineers, Derby, Eng.

hammer, for closing the grain and for strengthening alloys before they are rolled into sheets, is in an adjacent building. A press is also being prepared for punching disks up to 12 in. diameter. Two annealing furnaces or muffles are also provided, 5 ft. by 12 ft. and 7½ ft. by 14 ft. These are a most important item in the plant for either rolling or hammering metal. Slabs 24 in. wide by 1¼ in. thick are broken down hot, after being heated in the muffle. They are afterwards again heated when necessary between the successive passes to reduce them from 1¼ in. thick to ¼ in. Most of the rolling itself is done cold; and in some cases, especially when very pure aluminum is used, even the breaking down can be done cold. Connected with the rolling-mill is a pickling-shop containing tanks 12 ft. by 3 ft. charged with caustic soda, water, nitric acid, sulphuric acid, etc.; the pickling process is an important step in the rolling of aluminum, and has to be carried out whenever a good polish is required on the finished sheets, while it is also equally adapted when a matt surface is desired.

Fitting-Shop, Testing Machine and Laboratory.—The fitting-shop is sub-divided into several buildings, and is provided with a quantity of ordinary lathes, circular and band saws, a nicking machine, shaping machine and a number of small presses for cutting blanks out of sheet metal. In another building next to the rolling-mill there is a cold saw to cut metal 20 in. thick, especially used for cutting heads off aluminum bronze castings which cannot be handled or cut up in any other way. If the bronze is made hot, it can be forged into any shape. Most of it has a tensile breaking strength of 30 to 35 tons per square inch, and it is useless trying to handle the heads in any other way than by sawing. The Milton factory contains also a 30-ton Wicksteed testing machine, in which the different bronzes and light aluminum alloys are constantly being tested. There is also a chemical laboratory in which the sample tappings from the furnaces at Foyers are analyzed and records preserved, so that the purity of any particular delivery can always be ascertained. The whole works are lighted electrically from two dynamos, and a motor is kept ready for occasional assistance in driving the machinery.

Working of Aluminum.—With certain limitations, imposed by the chemical and physical peculiarities of the material, aluminum can be worked much like the other industrial metals handled at the present day. It is best melted in sand or in iron crucibles, without the addition of any flux, at a temperature not greatly exceeding its melting point, 655 deg. C. = 1,210 deg. F. On a larger scale the operation can be carried out at a dark-red heat on the bed of a reverberatory furnace lined with basic magnesia bricks of good quality. In casting, special precautions must be taken to allow for the great shrinkage during cooling. The molds should have large risers and plenty of vents. They are preferably cooled from the bottom upwards to enable the gases to escape. Slabs for rolling must be cast in closed ingot molds with a perfect machined internal surface which is coated all over with graphite and water; the molds must be very hot, and the castings cooled quickly in very cold water to make them soft. Aluminum can be forged hot or cold, preferably at a temperature which causes a hard wooden stick to smoke when pressed against the metal. In comparison with other metals it ranks third in order for malleability and sixth for ductility; sheets have been hammered as thin as $\frac{1}{40000}$ in., and wire can be drawn down to $\frac{1}{250}$ in. diameter. No lubricant should be used for rolling, and the aluminum requires frequent annealing at a low red heat just visible in the dark. In turning, the edge of the tool soon becomes blunt unless only small cuts are taken; the cutting speed should be high, and both tool and metal should be lubricated with turpentine or petroleum. Filing is best done with single-cut files because cross-cut files rapidly become choked. Spinning is easy on wooden or metal forms, the best lubricant being stearic acid dissolved in turpentine. Aluminum can be stamped or pressed, hot or cold, either dry or with soap water, for heavy work, and with tallow for small goods. Frosting is effected by dipping the articles for a few seconds in a hot 10 per cent. solution of caustic soda, containing about 2½ per cent. of common salt, till the surface turns black, then brushing in cold water and dipping in strong nitric acid till the metal becomes white again, and finally washing and drying in sawdust. This process is desirable before aluminum surfaces can be efficiently painted or enamelled. For polishing, a mixture of olive oil and rum is used, or emery and tallow, followed by rouge and turpentine. Burnishing is done with bloodstone or steel dipped in rum and oil, or in a solution of borax containing a little ammonia. To engrave aluminum the plate must be coated with stearic acid and turpentine or with rum and oil as before; if this be not done the graver slips continually.

Alloys of Aluminum.—Among binary alloys especially it has been found that, as the proportion of the two ingredients becomes more and more equal, the products lose their valuable qualities, and that the industrial alloys may be broadly separated into two kinds—namely, "light" alloys containing 90 to 99 per cent. of aluminum with 10 to 1 per cent., or even less, of some other metal or metals, and "heavy" alloys, containing 1 to 10 per cent. of aluminum with 99 to 90 per cent. of the other components. They can, therefore, be regarded either as pure aluminum strengthened by the addition of some other metal, or as one of the older metals improved physically and chemically by the addition of aluminum. A considerable amount of attention has consequently been devoted at Milton to the preparation of different sorts of alloys, some of which may be briefly referred to.

Light Alloys of Aluminum.—In its purest form aluminum is very soft and not of great service in those arts in which much rigidity and strength are required. For this reason a metal containing only 98.5 to 98.8 per cent. of aluminum, the impurities being silica and iron in almost equal proportions, is preferred to a metal of 99.6 per cent. purity. One casting alloy, having a specific gravity of 2.9, is largely used just now, and is known as "No. 6." Its composition is still kept secret. It has been found to produce remarkably clean castings, which require very little machining to finish up; it takes a high polish, and so far has given complete satisfaction. Another alloy is "No. 4," which contains nothing but aluminum and a small proportion of copper; it is not one of the materials generally recommended, though it has some good qualities. There is a strong suspicion that when aluminum is alloyed with copper galvanic action is set up between the two, especially when the alloy is exposed to salt water; therefore this is not recommended in any quantity for outside positions. The two alloys particularly recommended as among the best yet made are called "Wolframinium" and "Romanium." These are both ternary alloys, and next to the aluminum, tungsten is the leading ingredient in each. In one of them copper is present to a small extent, in the other nickel, and both have given astonishing results as regards strength and elongation. Samples of rolled sheet or rods made of these alloys have shown as much as 20 to 22 tons tensile strength per square inch, with 5 to 10 per cent. elongation in 4 in., which is remarkable when the low specific gravity of the material is taken into consideration. The above are all so-called "light" alloys—that is, alloys containing a preponderating percentage of aluminum with only a small quantity of another metal or metals.

CATHODE JETS.*

BY. C. E. S. PHILLIPS.

A Crookes tube in which the pressure has been so far reduced as to make it difficult for a discharge to pass, provided also that the negative electrode is suitably placed in a bulb of soda glass, often appears speckled with a number of vivid green flecks when strongly excited by the discharge from an induction coil. Sometimes, too, such an appearance is noticeable in the case of a highly-exhausted focus tube.

Considerable uncertainty, however, seems to exist as to the origin of these irregular green patches that form upon the inner surface of the glass, and while to day they are generally thought to be due to an emission from the cathode itself, the question does not appear to have been very definitely settled experimentally. In order, therefore, to demonstrate that the cathode is capable of emitting a radiation which can produce these effects, a glass bulb was blown and an aluminum disk sealed into it.

The disk, loosely placed upon a spindle and free to rotate, was held in position by two brass nuts; from its edge there projected a fine glass rod to the opposite end of which, by means of platinum wire, a small piece of thin sheet iron was securely attached. Such an arrangement afforded a means of rotating the cathode disk by the application of an external magnet.

The anode was placed in the side tube through which the bulb was exhausted. With this apparatus the best conditions for producing the green flecks were found to be: (1) a low pressure within the tube—sufficient to ensure an emission of X-rays, or, at any rate, a general fluorescence of the glass; (2) sudden stimulation; (3) particular spark length, and (4) a dry atmosphere.

It should be pointed out that, in the particular tube used, the cathode disk was somewhat roughened at its edge. Under favorable circumstances upon stimulating this tube and obtaining the well-known glow of golden-green upon the inner surface of the glass, a few vivid patches soon made their appearance; the magnet was then applied, and both cathode and patches moved one with the other.

Care was taken in this, as in subsequent experiments, to determine the extent of the direct action of the magnet upon the green spots, and in all cases that was found to be comparatively negligible. But it was further noticed that the patches would often remain luminous after the discharge had ceased to pass in the tube, and in some cases, curiously, even when the connecting wires were removed from the apparatus, and with both electrodes earthed, the patches still continued to glow for as long as 10 secs. When the magnet was applied as before it was interesting to observe that such patches moved as they did when the discharge was passing—a result indicating that even under these conditions, and when no free charge resided upon the electrodes, there was still a jet of electrified matter issuing from the cathode.

In the course of this work the writer noticed that it was possible to deflect these cathode jets both electrostatically and magnetically, and that the direction of such deflection in the latter case, for a given pole, corresponded with the deviation observed in the green-producing rays of the cathode stream under similar circumstances.

The flickering green patches were also easily obtained by using an ordinary sewing needle as the negative electrode, and when making use of such an arrangement, it was seen that occasionally a large green patch—say the size of a three-penny piece—could be scattered and broken up into a number of smaller spots by suddenly increasing the potential difference between the electrodes. Moreover, when an arcing or some such disturbance was caused to take place between a jet-emitting cathode and an-

* From the *Electrician*, London.

other body placed very near to it and also within the tube, all patches immediately disappeared from the glass. It was found as well that placing tinfoil upon the outside of the glass near to the cathode prevented the formation of the jets. May not these facts go some way to account for the curious variation in the nature of the X-rays referred to by Mr. Porter and others, when spark gaps were placed in series with the focus tube, or metal caps placed round the outside of the glass in the neighborhood of the cathode? Such a device would, in view of the above results, be expected to influence the tendency which there appears to exist for the cathode to give off jets from its edge, and indirectly in this way to modify the nature of the focused stream from that electrode. It should be understood, however, that a spark gap arranged in series with the tube did not appear to materially affect the formation of the green spots, but since a particular potential difference at the electrodes, together with suddenness of stimulation, are important factors in the matter, it appears reasonable to conclude that the tendency of the cathode to emit the jets would, under such circumstances, certainly be affected to some extent.

At any rate it is probably important to see that the concave cathodes of focus tubes have a fine polish, particularly at their edges, and especially if they are to be placed in highly exhausted bulbs for the production of X-rays.

Electrically Produced Phosphorus.

The electric furnace has enabled of phosphorus being successfully produced in several different ways. One method consists in heating a mixture of phosphate of lime and coke, the two ingredients first being finely powdered. On the mass becoming pasty, the openings of the furnace are sealed, except one through which the vapor passes, which is then collected and distilled in the usual way.

CANADIAN NOTES.

Ten months' earnings of the Montreal Electric Street Railway amount to $1,179,284.63. For the same period last year the earnings of the railway were about $100,000 less. During the month just closed, the figures are unprecedented, over $144,000 having been collected, giving an increase of about $15,000 over the corresponding month last year.

It is reported that the Ottawa Electric Railway Company is negotiating for the purchase of the Gatineau Valley Railway and will convert that road from steam to an electric railroad. The country through which this line passes is of the grandest in Canada, and it is in the Gatineau Valley that the famous fishing grounds are situated.

Nelson Moore of Guelph, Ont., has completed a model of his overhead electric railway. The hardwood posts from which the cars are suspended, as well as the base and the arms, are incased in steel and strongly riveted to prevent vibration. The iron sockets are suspended from the arms of the post and into these steel rails are laid. The wheels of the car are built after the manner of bicycle wheels, with steel spokes and ball bearings, which gives strength and lightness and ease of motion. The framework of the car will be of strong iron or steel, and the car is suspended from the wheels to a distance of three feet from the ground. The interior is fitted with back-to-back seats which run the entire length through the middle and are suspended from the top. The inventor claims many advantages for his overhead road. No grading or ground work has to be done in constructing the road; no bridges are required to span streams or cross ditches and ravines—a material consideration. Then in the winter time there would be no clearing away of snow from the tracks, and for the same reason no washouts. Mr. Moore claims that less electric power would be required to operate the cars in comparison with the present systems, that greater speed would be obtained and more effective locomotion secured.

LONDON NOTES.

[From our London Correspondent.]

Electricity for the "Underground."

The directors of the much-abused Metropolitan Railway Company have now made an official announcement regarding their intentions in the matter of electrical equipment. The want of ventilation of the underground tunnels has been a trouble to the company for many years past, and negotiations have repeatedly been opened with English and foreign electrical men and promoters with a view to working the lines electrically and thus overcoming the ventilation difficulty. These negotiations have failed to come to a satisfactory conclusion until within the past month or so. The latest and official intimation is that the Metropolitan and Metropolitan District railway companies (which in places traverse the same lines) have agreed for an experimental working by electricity of a portion of their line situated between High street, Kensington and Earl's Court stations. The estimated cost of the experiments is about $100,000, which will be borne in equal proportions by the two railway companies. It has been stated that the trials will extend over about two years, by the end of which period it is expected that there will be additional experience of the Waterloo & City electric line, which has just been opened, and probably others as well.

Middlesbrough (Eng.) Electric Trams.

What is considered by English engineers one of the most important, if not *the* most important piece of electric tramway work of the past year or two, has just been completed and opened. The line connects the towns of Middlesbrough, Thornaby and Stockton. For English work the lines have been very rapidly constructed, the entire permanent way of fifteen miles of track being completed in less than six months. For a distance of six and one-half miles the track is double and for two miles single. The tracks are laid on a 3-foot 6-inch gauge and paved with whinstone and granite sets and with scoria blocks. The steel rails, in 30 to 36 feet lengths, are 6-inch girders, 92½ lbs. to the lineal yard. The rails are longitudinally bonded with double copper bonds (Columbia 0000), and at intervals of 120 feet the tracks are also cross-connected by copper. The gradients are not particularly difficult, though at one point they are 1 in 18. The overhead wire method is employed, center poles being used for certain roads within the town of Middlesbrough, while all the remainder of the route is fitted on the side pole and bracket system. The trolley wires are of 000 hard drawn copper .364 inch diameter and divided by sectional insulation. There are overhead points and crossings at the ends of the lines and at the branches leading into the main and sub-stations. Section pillars are placed at each half mile section on the road. They are about 4 feet high and are placed on the curb lines. They are fitted with switches, for cutting out a section of the trolley line or feeder as may be desired without interfering with other parts of the line. The motor cars are mounted on four-wheeled bogie trucks of the maximum traction type, each truck carrying one G. E. 800 motor, a k2 series parallel controller being fixed at each end of the car.

The main power station has been erected at Stockton-on-Tees. In the boiler room there are three Babcock & Wilcox water tube boilers, each having a heating surface of 3,580 square feet and being capable of evaporating 12,000 lbs. of water per hour. Each boiler furnace has a Vicars mechanical stoker worked by an electric motor. There is a 240 tube Green economizer used. The engines are three in number and are of the Reynolds-Corliss horizontal cross-compound condensing type of 400 HP. each. These were made by Messrs. Allis & Co. of Milwaukee. They have cylinders 16″ x 32″ x 36″ stroke. Each engine runs at 94 revolutions per minute and is directly coupled to a 300 KW. three-phase generator. The condensing and pumping plant is arranged on the basement floor, and all steam, condenser, suction and other pipes and connections being also carried below the floor line, a clear space is thus obtained round the engines and generators. The three alternators are 32 pole, 2,500 volts, giving a frequency of 25 cycles at 94 revolutions per minute. The fields are excited from the 500 volt bus-bars. To supply light when the machinery is at a standstill and also to start the dynamos a battery of Tudor cells has been provided, consisting of 260 cells with a discharge rate of 48 to 70 amperes, the capacity at the lower discharge being 240 ampere-hours. A booster is connected in series with the 500 volt bus-bars for discharging these cells. It consists of a rotary converter fed from step-down transformers of special design. Each transformer has the primary and secondary separated to give the effect of a considerable reactance, this arrangement giving a large range of voltage on the rotary converter to provide for the alteration in the charging volts required by the cells. The rotary converters consist of direct-current generators, to the armature winding of which connections are made at suitable points to a set of three collector rings on the end of the shaft opposite that occupied by the commutator. The same winding serves both for alternating current led into the machine and for direct current taken out. A 500-volt continuous current direct from the rotary converters in the main station feeds the overhead conductor for two miles on either side of the station, while the Middlesbrough and Linthorpe sections are fed by a current transmitted at 2,500 volts from the main station to the sub-station at Newport where it is transformed down to 500 volts for the line. The feeder cable consists of two concentric cables having three conductors of .0775 square inches area. With this small section it is possible to transmit 300 KW. with less than 5 per cent. loss. The two four-pole rotary converters of 200 KW. capacity running at 750 revolutions per minute, in the main power house, feed direct into the portion of the lines from that point and three similar machines are located at the sub-station from which distribution is made to the remainder of the system. At the station there is a combination of static and rotary transformers for charging the batteries, the charging current being passed through the rotary and the voltage raised from 500 to 650 volts for charging. As there are no direct-current primary generators in the power house, a rotary converter was designed to supply the difference between the line voltage and the variable voltage required for charging. Combined with this was a static transformer having a ratio of transformation of 330 volts to 80 volts on a non-conductive load. The transformer was designed with a large amount of leakage between the primary and secondary, the leakage being adjusted so that by changing the phase of the armature current by variation of the field current of the booster the transformer ratio is varied and consequently the voltage on the collector rings. In this way it is possible to vary the voltage on the continuous side of the rotary from 40 volts to 150 volts. The charging current is 60 amperes. The armature of the rotary is designed to carry 60 amperes continuously.

The Middlesbrough & Stockton line is owned and operated by the Imperial Tramways Company, whose managing director and engineer, Mr. J. Clifton Robinson, C. E., M. I. E. E., has been so actively connected with the equipment of other English and Irish lines with electric traction. The installation of the electrical plant has been specially supervised by Mr. H. T. Parshall as consulting engineer for the contractors.

LEGAL NOTES.

A dismissal on the trial of Thomas Taylor's suit against the Nassau Electric Railroad Company, Brooklyn, N. Y., for damages for his ejectment from one of its cars, has been reversed by the Second Appellate Division. A car on which Taylor had taken passage had become disabled, and it was detained for repairs. Taylor, unwilling to wait, boarded another car, after he was cautioned by an officer of the company that he would be required to pay a new fare. Refusing to do so, he was forced to leave it. He had shown that the delay caused by the condition of the car he first took resulted in a loss of $4, through his failing to keep an engagement in New York. Justice Woodward, who gave the opinion, though holding that plaintiff could not recover damages for ejection, said there must be a reversal because it was shown he was damaged in the sum of $4. "The plaintiff," the court said, "entered into a contract with the defendant to carry him between two points upon the line of railroad operated by the defendant with reasonable speed and in safety. The fact that one of the cars operated by the company met with an accident did not give the plaintiff any new rights. The defendant had a right to transfer him to another car if it thought proper to do so, but because of the fact that the defendant did not elect to do this, the plaintiff gained no right to transfer himself. The defendant, by refusing to make the transfer, took upon itself the responsibility for its breach of contract. The plaintiff had notice that he could not retain his seat in the second car of the defendant upon the original payment of his fare, and the company by neglecting or refusing to carry him within a reasonable time simply became answerable for the damages which he sustained by reason of the failure of the defendant to carry out its contract."

At Saginaw, Mich., on the 25th ult., in the case of the city of Saginaw vs. the Union Street Railway Company, the Saginaw Consolidated Street Railway Company and the Boston Safe Deposit & Trust Company, and the Boston Safe Deposit & Trust Company vs. the Saginaw Consolidated Street Railway Company et al., testimony was taken and a decree of foreclosure granted. In the case of the Boston Safe Deposit & Trust Company, trustee, vs. the Saginaw Consolidated Street Railway Company and Union Trust Company of Detroit, the decision dismisses the injunction and provides that the property shall not change hands until all of the indebtedness of the companies to the city shall be paid, and permits the running of cars on all lines.

The American Street Railway Association Convention.

The following card addressed to members of this Association has been sent to us for publication:

CHICAGO, Aug. 1, 1898.

Dear Sir: I desire to remind all our members that the next meeting of this Association will be held at Mechanics' Association Hall, Huntington avenue, Boston, Mass., September 6, 7, 8 and 9, 1898. We expect to have the largest Convention we have ever held. Papers will be read on live subjects. The exhibits will be a prominent feature of the meeting. Full particulars in regard to hotels, railroad rates, etc., were given you in circular of May 1. In order to secure reduced fare you *must* get a certificate from the agent when you purchase your railroad ticket. Headquarters at Hotel Brunswick. Hoping to have your company represented, I remain yours very truly,

T. C. PENINGTON, Secretary and Treasurer.

The American Association for the Advancement of Science.

The annual meeting of the American Association for the Advancement of Science will be held at Boston from August 22 to 27. The meeting promises to be an important one as a number of well-known scientists are expected to be present. The electrical department especially will be ably represented, and a number of important papers on electrical subjects are announced in the programme. The headquarters of the council, which will meet on August 20, will be the Copley Square Hotel.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING PLANTS.

Boston.—The roof of the new power house of the Boston Electric Light Company, in process of construction in South Boston, collapsed at 5:55 P. M. on the 29th ult., burying six men under a mass of iron, brick and timber. Two of them were taken out dead and the other four were badly injured. Three different theories regarding the cause of the accident have gained credence. One is that the immense iron crane used for hoisting machinery and which is supported on the outer wall of the western section and the brick dividing wall was so heavy that its weight weakened the support to the roof. Another theory is that the fire brick between the girders, which was only protected by a thin layer of tarred paper and laths, absorbed so much water during the rain the three preceding days that the weight could not be borne. Still another reason suggested is that the heat expanded the iron work to an unusual degree, which caused it to give way. The Building Commissioner is investigating the matter.

Cleveland, Tenn.—The Cleveland Water & Electric Light Company's plant has been purchased at receiver's sale by W. W. Cunnyngham for $36,500.

Duluth, Minn.—Last week we gave an estimate, handed in by City Engineer McGilvray, of the cost, etc., of a 500 arc light plant under city operation, which amounted to $27,710. Mr. William Burgess, in a letter to the "Herald" shows that the city engineer's estimate is misleading and the figures altogether too low. "To maintain a municipal electric lighting plant of 500 arc lamps, distributed to light the city to advantage," Mr. Burgess says, "will cost as follows: One superintendent, $1,800; one chief engineer, 1,200; one assistant, 900; two firemen, 1,440; two oilers, 1,440; two dynamo tenders, 1,440; one repair man, 900; two linemen, 1,800; one night foreman, 960; two inspectors, 1,440; nine trimmers, 6,480; maintenance of horse and wagon, 300; incidentals, including oil and waste, 1,200; coal, 8,000; carbons, 4,500; depreciations, 4,500; interest on 150,000 at 4 per cent., 6,000; maintenance of poles, wires and lamps, 2,000; insurance on 60,000 station, 960; liability insurance, 1,000; one bookkeeper, 720; making a total of $48,980. Divide this by 500, the number of lamps, and it gives you a net annual cost of maintaining a lamp of $97.96. This estimate is based on arc lamps of 1,200 candle power and a modern up-to-date plant. Should old style apparatus be used it would increase the cost of maintenance. The locating of the plant would also have its effect on cost of operation. The writer has placed the cost of building a plant of this size at $150,000, which is not sufficient to build an economical up-to-date plant." Mr. Burgess adds that he "has figured on the best economy in operating, which is seldom found in municipal lighting."

Ellisville, Miss.—The establishment of an electric light plant is in contemplation by the authorities of this town.

Framingham, Mass.—A committee appointed to investigate the electric lighting system has reported against the purchase or establishment of a municipal plant. They say the price the town is paying for its lights under contract appears to be about the average price paid by other municipalities for similar service.

Hampton, Va.—W. J. Payne of Richmond has closed an option for the purchase of the plant of the Chesapeake Light & Power Company. It is presumed the electrical machinery in the plant will be added to and the plant be converted into a power house for propelling the cars on the new electric railway, in which Mr. Payne is also heavily interested.

Kokomo, Ind.—A cylinder exploded at the power station of the Citizens' Electric Company on the night of the 28th ult., killing George Dunning, the engineer, and badly damaging the plant.

San Bernardino, Cal.—The proposed consolidation of all the electric and gas plants from Redlands to Los Angeles, including the transfer of the San Bernardino Company to the Redlands Electric Power Company, has failed for the present as far as the San Bernardino Company is concerned, owing to a raise in the assessments by the county officials. A new schedule of prices has been issued that raises the price of gas from $3 to $4 per thousand and for incandescent lights $1 per month for all night, 75 cents until midnight, 60 cents to 10 o'clock and 50 cents to 9 o'clock. This is a raise of 100 per cent. in some cases. The arc lights are $9 per month for all night, $7 to midnight, and $6 to 9 P. M.

South Norwalk, Conn.—Commercial electric lighting under municipal ownership was formally introduced in South Norwalk on the 1st inst., when the incandescent lamps of the new system were turned on for the first time and burned throughout the evening. It is the only municipal commercial plant in the State, although South Norwalk has lighted its streets for three years. The new order of things has met with considerable opposition from the private company established in Norwalk and an injunction is now pending.

Sycamore, O.—This village has decided to have an an electric light plant and waterworks system, and expects to have both in operation within eighty days.

STREET RAILWAYS.

Akron, O.—Suits for damages, aggregating $105,000, were begun here on the 1st inst., against the Akron, Bedford & Cleveland Railway and the local street railway for injuries received by the tipping over of a car near Silver Lake, June 21. Mrs. Schumacher asks $50,000; Mary Rankin, $50,000 and Jennie Shepard, $5,000. All live in Akron.

Albany, N. Y.—The State Railroad Commission on the 3d inst. granted an application of the Third Avenue Railroad Company of New York for permission to change its motive power to underground electricity on all the lines now operated by cables. The Commission on the same date granted the application of the Peekskill Traction Company for permission to construct an electric street railroad in Peekskill. The road will run to the State camp and thence to Verplanck's Point.

Auburn, Mass.—The Worcester & Webster Electric Railway Company has accepted the franchise granted by the Auburn selectmen, and engineers are at work on the survey.

Berlin, N. H.—The Railroad Commissioners have made a favorable report on the petition of the Berlin Street Railway Company for a charter for an electric railway in Berlin and Gorham. The report will go to the court for approval. The proposed road will be 5½ miles long.

Birmingham, Ala.—The North Birmingham steam dummy line is being converted into an electric road and work will be pushed so as to have the line ready for operation by October 1. There is every reason to believe that the day is not far distant when the Highland Avenue & Belt Railroad will be transformed into an electric line. Then only one steam dummy line will penetrate the city, and that line is more of a railroad than dummy line, being the one which goes to Bessemer.

Boston.—The Railroad Commissioners have approved the plans of Engineer Kimball of the Boston Elevated system so far as they show the proposed form and method of construction of the stations and approaches thereto, the track system with walls and band rails, also the contact rail and guard. The cars are to be run by electricity by the "third rail" system, only the contact rail, instead of being in the center of the track, is placed outside, elevated slightly above the track rail. Between the tracks the entire length of the road will be a platform on which passengers may walk in case of accidents, etc.

Chagrin Falls, O.—The Cleveland & Chagrin Falls Electric Railway Company has a large gang of men and teams at work just east of town on the extension of its line through Geauga County, which will be known as the Chagrin Falls & Eastern. The entire right of way to Burton, 18 miles into the country, has been secured, and the company announces that the line will be completed early in September.

Charleston, S. C.—The new electric railroad of the Charleston & Seashore Railway Company, running from Mt. Pleasant to the Isle of Palms, has been completed and was opened to public traffic on the 29th ult. Connection is made with Charleston by a ferry boat furnished with all modern appliances.

Delaware, O.—After four attempts, made at different dates, to sell the Delaware Street Railway at public auction, Receiver Cone finally succeeded on the 30th ult. in disposing of the property at public sale. It was bought by B. W. Brown and others of this city for $13,525. The road originally cost $40,000 and was appraised at $15,905.

Elizabeth, N. J.—Among the bids submitted on Thursday last to the Union County Board of Freeholders for a franchise for a trolley line on Westfield avenue (the proposed boulevard) from Elizabeth to Plainfield, was one for $250,000, signed by John Kean, acting in the capacity of president of the Elizabeth City Horse Railroad Company. Another bidder offered $200,000. The franchise is to extend seventy-five years. The freeholders are to meet on the 10th inst. to act upon the bid.

Fairfield, Me.—The route planned by the engineers for the Benton & Fairfield Electric Railroad has been approved by the Railroad Commissioners and the road will be built at an early day.

Flushing, N. Y.—A new trolley company has been formed to build an electric road from Flushing to Jamaica, and to connect several villages on the south shore of Long Island. At Jamaica a connection will be made with the road running to Far Rockaway, with extensions leading to Hewletts, East Rockaway, Lynbrook, Rockville Centre and Freeport. The capital stock of the company is $150,000, and the corporation will be known as the Flushing & South Shore Railroad Company. The directors are William F. Brown, William L. C. Allen, Louis E. Freeman, Francis S. White, Edward J. Boyle, George A. Hamilton, William J. Howson, Matthew J. Kearney and J. H. Gibson.

Great Barrington, Mass.—A trolley line to run from Canaan to Great Barrington through New Marlboro is now proposed. A part of the route has already been surveyed, and it is of easy grade. It will pass through several villages which at present have no communication with the larger towns except by private teams or a daily stage.

Hackensack, N. J.—The block in the extension of trolley transit through Bergen County, caused by the inability of the Bergen Traction Company to pass through Englewood to the west and by the obstructions

to trolley schemes encountered in Hackensack, is now to be removed, and a step taken which, in a few years, will result in the joining of all the Bergen County towns with those of Passaic, Essex and Hudson Counties as well as with New York City, via Fort Lee ferry, by electric cars. Right of way has been obtained for a trolley line within the limits of Hackensack.

Hamilton, Ont.—Municipal ownership of the street railway did not succeed at the election in Hamilton on Wednesday last. One of the reasons given by the "Spectator" was that the property owners did not desire to trust the city council with the running of the railway.

Havelock, Neb.—The proposition submitted by the Lincoln Traction Company for a street railway in this town was carried by a large majority at an election called for the purpose.

Lansing, Mich.—The Michigan & Indiana Railway Company, which will connect Benton Harbor, St. Joseph, Niles, Berrien Springs and other points in Berrien County, filed articles of association on the 27th ult. The new company has obtained right of way through all the townships from St. Joseph to Niles.

Lawrence, Kan.—Representatives of Chicago capitalists have been looking over the ground here and have held several conferences with leading citizens with a view to the construction of an electric street railway in the city, and the probability is that a line will soon be built.

Montclair, N. J.—The North Jersey Street Railway has opened the new branch of their system giving Montclair and Caldwell connections. The completion of this line makes it possible to take a moonlight ride these hot nights from the terminals of the system in Jersey City and Newark to points in the Passaic Valley famed for their beauty.

Nantasket, Mass.—The new Nantasket trolley road in which President Andrew Radel of the Bridgeport, Conn., Traction Company is chiefly interested, was auspiciously opened last week. The road is to be 60 miles in length, 10 miles of which have been completed.

Owosso, Mich.—E. M. Hopkins of Chicago, acting as the representative of an Eastern syndicate, has succeeded in arousing earnest interest among citizens of means in Vernon and the other towns concerned in the proposed electric road to be known as the Caledonia, Venice & Vernon Electric Railway, and the project seems reasonably certain of being carried out. The proposed line runs east from Corunna and south through Vernon into Durand. The road will run through a rich and prosperous farming country and promises to be a profitable investment. Combined with the Owosso & Corunna Traction Company's line, there will be about eighteen miles of track.

Petersburg, Va.—The city council at its meeting on the 1st inst. adopted an ordinance giving the Piedmont Traction Company of Charlottesville, Va., the privilege to construct and operate a street electric railway on certain streets in this city. Under the ordinance the company is to begin the construction of the railway within six months.

Portland, Me.—The Portland and Yarmouth Electric Railway has been completed and cars are running. The road runs through eight miles of beautiful scenery and will become very popular with Portland people as a pleasure trip.

Richford, Vt.—The electric railway from this town to Montgomery, for which a charter has been granted, has many warm advocates in both places and the promoters are sanguine of its success. It may probably be built this fall.

Tonawanda, N. Y.—The electric locomotive for use on the Buffalo & Lockport line has arrived in this city from the General Electric Car Works at Schenectady, and will soon be put in use for drawing freight along the new electric line. It is double ended and in appearance resembles an ordinary yard engine.

MANUFACTURING, ETC.

Cleveland, O.—The recent fire at the Lincoln Electric Company's works here did considerable damage, but did not disable the company to such an extent as to prevent an early resumption of its business. The company has obtained more commodious quarters in the World Building on Ontario street, and is already in full operation and prepared to take care of all orders.

Fond du Lac, Wis.—The Central Operating & Construction Company is a new corporation which has been organized in this city with Maurice McKenna, C. D. Smith and Menzo Smith as incorporators. According to the articles of incorporation the company's plans are to cover a wide territory. It is to include a water works system, a gas and electric lighting plant, a street railway and a boat line on Winnebago lake.

Iron Mountain, Mich.—Detroit capitalists are erecting a plant near here for the making of steel billets and pig iron direct from the ore by a secret process. They claim it can be done at a very small percentage of present cost. If the furnace is a success it will revolutionize the iron business and give a market value to many millions of tons of lead ore on this range. The demonstration furnace, together with engine and electric motor, will cost $12,000.

New York.—The "Journal of Commerce" says: "Orders for upwards of $12,000 worth of electrical supplies and three large pieces of metal working machinery for Genoa, Italy, have just been received by a merchant in the Chesebrough Building. The volume of business in manufactured articles that could be developed with the Italian market, it is believed by those in a position to know, is not thoroughly appreciated by American manufacturers. The question of extending credit to Italian merchants need not be considered; make your wares known in that market and advise importers there to send their orders through exporters or bankers here. The quantity of American goods taken into Italy through German and English merchants ought to be fully realized in order that merchants and manufacturers here should know what the proportion of the business is. As to this, one of the few Italian exporters expressed himself yesterday, saying that there are many needs which could be supplied directly from here to the Italian market just as advantageously as from Europe."

Philadelphia.—The Pennsylvania Manufacturing, Light & Power Company, which recently purchased the Hestonville Railway Company's power house at Twenty-fifth and Callowhill streets, is making arrangements for enlarging the station and converting it into one of the largest power plants in the country.

Washington, D. C.—Commercial Agent Stern at Bamberg, Germany, writes that the United States electric machinery (Walker Company, Cleveland, O.,) used in the electric street railway of Bamberg is giving entire satisfaction. This means a good deal, the Consul says, considering that one of the largest works for electric engineering in Germany (Schuckert, at Nuremberg,) is within close proximity.

TRANSMISSION PLANTS.

Vineland, N. J.—Capitalists and business men are forming a company to dam Muddy Run, four miles from here, for the purpose of furnishing electric power for manufacturing purposes and lighting the town with electricity.

COMPANY MATTERS.

Cincinnati.—The Cincinnati, Hamilton, Middletown & Dayton Street Railroad Company has changed its name to the Mill Creek Valley Street Railroad Company. L. C. Weir is president and O. B. Brown secretary of the corporation.

Hoboken, N. J.—The Hudson Electric Light Company of Hoboken is reported to have passed into new hands. The controlling stock in the company was formerly held by the General Electric Company and a few foreign stockholders. B. M. Shanley, president of the Consolidated Traction Company; Myles Tierney, president of the North Hudson County Railway Company, and E. F. C. Young, president of the North Jersey Street Railway Company, are said to be among the new owners. The company supplies Hoboken and the towns in the northern part of Hudson County, N. J., with electric lights.

Philadelphia.—Thomas Dolan, president of the United Gas Improvement Company, has purchased a controlling interest in the West End Electric Company for the Pennsylvania Manufacturing Light & Power Company of which he is a director. The fact that Mr. Dolan made the purchase gave rise to a report that the West End had been acquired by the United Gas Improvement Company, and that it was a preliminary move to an early absorption of the Pennsylvania Company by the United Gas Company. There is not, Mr. Dolan states, the slightest truth in the latter report, nor is such a consolidation now in contemplation.

NOTES FROM A CORRESPONDENT.

Albany, N. Y.—On September 1 the new law enacted by the last session of the Legislature in regard to transfers will go into effect. This law provides that no transfer ticket over anything giving the right of transfer from a public conveyance operated upon a line route of a surface railroad or from one to another of the same line shall be issued, sold or given except to a passenger entitled thereto, and any person who shall so give, sell or receive and use such transfer shall be guilty of a misdemeanor.—The State Railroad Commission has granted the application of the Frankfort & Utica Railway Company permission to use the overhead electric trolley on its proposed line from Utica to Frankfort.

Schenectady, N. Y.—An employee of the General Electric works by the name of Swartz was recently killed by electricity as the result of stepping on the experimental third rail electric railway of the company. He tripped and fell across the rails in such a way as to complete the circuit and receive through his body a continuous current of 500 volts. His death was instantaneous.

Troy, N. Y.—The report of the Troy and New England Railway Company shows assets of $372,500, including $370,532 for cost of road and equipment. The liabilities include $189,000 capital stock and $183,900 funded debt.

ELECTRICIANS IN THE WAR.

New York.—The First Regiment of Volunteer Engineers, Col. Eugene Griffin commanding, has finally received orders to proceed to the front. The regiment embarked on Thursday last on the troopship Chester. They go to Porto Rico, and Col. Griffin said he expected to report to Gen. Miles by Friday of the present week. The officers and men of the regiment were much pleased at the prospect of soon getting within range of the Mauser rifle.

PERSONAL AND MISCELLANEA.

Harry A. Ward of Oneonta, N. Y., a graduate of the class of '98 in the course of electrical engineering at Cornell University, has been appointed superintendent of the Oneonta & Otego Valley electric road.

Most of the Maine electric roads have abandoned the plan of hiring an insurance company to stand its losses for it in case of accident whereby patrons are injured. When this system first went into vogue in the State, the rates were low and the trolley companies were anxious to hire this sort of protection. But after a year or two of experience with the cases that came up, the insurance companies rose on their rates in most drastic fashion.

M. Henri Moissan has succeeded in obtaining metallic calcium free from impurities. He dissolves the crude metal in molten metallic sodium, maintained at a red heat. On cooling, the calcium crystallizes and is separated by being treated with absolute alcohol. The crystals are white and shining and belong to the hexagonal system.

Capt. Clement A. Griscom, Jr., son of Clement A. Griscom, president of the International Navigation Company, who has recently returned from Cuba, met with a painful and peculiar accident in Washington, D. C., on Wednesday last. While in an F street business office his right hand came in contact with a rapidly revolving electric fan and one of the fingers was completely severed.

In reply to a letter from Miss Helen Miller Gould of the Women's National War Relief Association, inquiring whether there was anything in the way of supplies or apparatus that would contribute to the comfort of the sick and wounded on board the hospital ship Missouri, Major Arthur, surgeon in charge, said that four electrical kitchens were needed, the cost of which, he thought, would be between $500 and $1,000 each. Miss Gould at once informed Major Arthur that the association would furnish them. The Missouri is being fitted up at the foot of Amity street, Brooklyn, N. Y.

The Belt Line railroad, by which the trains of the Baltimore & Ohio Railroad runs through Baltimore, was rendered impassable for hours a few nights ago by the falling of a portion of the overhead electrical construction. The break occurred on both sides of the bridge at Huntingdon avenue. It was just about 9 o'clock when about 500 feet of the conductor, weighing perhaps seventy-five tons, with its supporting cables, broke loose from the giant supports, and fell with a tremendous crash, which was heard for several squares. When the conductor came in contact with the earth a brilliant electrical display was the result. There is a signal tower just west of Huntingdon avenue, and the operators were startled at seeing great electric sparks leaping from one switch lever to another. A warning was immediately sent in to headquarters, the current was turned off at the Howard street power house and Engineer W. T. Manning was soon on the scene with a wrecking crew, which worked during the greater part of the night to raise the heavy conductor and secure it to the giant support and trusses.

In about two months, says the Washington correspondent of the N. Y. "Herald," some miniature models of our battle ships and cruisers are to be placed in the experimental tank just finished at the Washington Navy Yard to the end that the speed and power of the big boats themselves may be accurately ascertained. "For," said Mr. William Denny, one of the most progressive and well informed Scotch shipbuilders, "the truth is that of all the problems about a steamship the only one at the present moment incapable of being solved by a priori methods in extreme cases is that of speed and power. No ability and no training will enable even the most skilful naval architect to overcome the want of an experimental tank in coping with these questions." The tank just completed is 500 feet in length and 50 feet in width, with water space of 475 by 43 feet and a depth of 14 feet.

RECENT COMPANY ELECTIONS.

Portsmouth Gas & Electric Light Company, Portsmouth, N. H.—President, H. Fisher Eldredge, to fill the vacancy caused by the death of his brother, Marcellus Eldredge. Calvin Page was elected a director.

Consumers' Light, Heat & Power Company, Elizabeth, N. J.—President, Albert B Carlton; vice-president, ex-Mayor John C. Rankin, Jr.; secretary and manager, A. H. Stephens. All the officers are residents of Elizabeth.

St. Albans Street Railway Company, St. Albans, Vt.—President, Col. E. C. Smith; clerk and treasurer, F. S. Stranahan; directors: H. M. Stevens, Col. E. C. Smith, W. B. Fonda, A. O. Brainerd and F. S. Stranahan.

Amesbury Electric Light, Heat & Power Company, Amesbury, Mass.—Directors: Dr. J. F. Spaulding, Salisbury; Dr. B. H. Young, Dr. J. Douglass, James Bakie, Jr., Ezra C. Morrill, Charles Goss, Amesbury, and Harrison Rowe, Kensington, N. H. Dr. Young was elected treasurer of the company.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

INCORPORATIONS.

The National Light & Power Company, New York—to manufacture the necessary apparatus and solutions for producing electric currents. Capital stock, $10 000, with the privilege of increasing the same to $5,000,000. The shares are $100 each, and are held by Edward S. Savage, Rahway, N. J.; M. D. Valentine, Woodbridge, N. J.; A. W. Sherman, Brooklyn, N. Y.; Albert Burns, The Bronx, N. Y., and A. L. Sherer, New York City.

The Sandusky & Interurban Electric Railway Company, Cleveland, O.—to build and operate an electric railway through Erie, Huron and Lorain counties, Ohio, connecting lines already in operation. Capital stock, $500,000. Incorporators: H. A. Everett, E. W. Moore, B. Mahler, C. H. Stewart and W. H. Price.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED AUGUST 2, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

608,178. Electrical Rail-Bond and Method of Securing Same in Place. William R. Cock, Plainfield, N. J. Filed Dec. 7, 1897.

608,258. Electric Bond for Railway-Rails. Samuel H. Harrington, New York City. Filed Dec. 10, 1896.

608,281. Trolley. Frank P. Case, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed June 30, 1897.

608,301 and 608,302. System of Train Control. Edwin W. Rice, Jr., Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Dec. 31, 1897, and March 26, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

608,259. Electric-Arc Lamp. Charles A. Pfluger, Chicago, Ill. Filed Aug. 7, 1895.

608,497. Electric Headlight Lamp. Harlan P. Wellman, Ashland, Ky. Filed Dec. 10, 1897.

ELECTRICAL MACHINERY AND APPARATUS.

608,191. Apparatus for Producing Traversing Motion of Overhead Traveling Cranes. John G. Fiegehen and Edward G. Fiegehen, Bedford, England. Filed Dec. 24, 1897.

608,246. Electrical Signaling Apparatus for Transmitting Commands. Conrad Arldt, Berlin, Germany. Filed Dec. 29, 1897.

608,249. Alternating-Current Induction-Motor. Charles S. Bradley, Avon, N. Y., assignor to the General Electric Company of New York. Filed Oct. 22, 1895.

608,277. Armature for Dynamo-Electric Machines. Edward H. Anderson and David P. Thomson, Schenectady, N. Y., assignors to the General Electric Company of New York. Filed Jan. 8, 1898.

608,299. Commutator. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed April 27, 1898.

608,307. Electrical Distribution. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed July 14, 1894.

608,308. System of Electrical Distribution. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company of New York. Original application filed July 14, 1894. Divided and this application filed May 22, 1897.

608,309. Regulating Dynamo-Electric Machines. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed April 23, 1898.

608,310. Automatic Switch for Regulating Electric Air-Compressors. Moss Moseley and Philip Funck, Rochester, N. Y.; said Funck assignor to said Moseley. Filed Nov. 15, 1897.

TELEPHONE AND TELEGRAPH APPARATUS.

608,333. Telegraphic Transmitting and Receiving Apparatus. Bernhard Hoffmann, Paris, France, assignor to Societe de International Telescriptor Syndicat, Limited, London, England. Filed May 5, 1897.

608,389. Rapid Telegraphic Transmission on Cable-Lines. Charles L. Davies, London, England. Filed June 25, 1896.

608,504. Telephone-Transmitter Arm and its Attachment. William J. Barr, Ashtabula, Ohio. Filed Oct. 30, 1897.

MISCELLANEOUS.

608,175. Reciprocating Electric Bell. Herman Casler, Canastota, N. Y. Filed March 18, 1898.

608,211. System of Heating by Electricity. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company, same place. Filed Nov. 16, 1892.

608,216. Battery-Zinc. Dora Ogden, Columbus, Ind. Filed April 12, 1897.

608,224. Galvanic Bath. Carl E. Schnee, Carlsbad, Austria-Hungary. Filed Sept. 14, 1897.

608,231. Insulating-Caster and Electric Switch Combined. Augustus W. Slayton, Tecumseh, Mich. Filed May 18, 1898.

608,300. Electrolytic Apparatus. John G. A. Rhodin, Eccles, England. Filed Aug. 11, 1897.

608,319. Electromechanical Lock. Henry G. Carleton, New York City. Filed Sept. 9, 1897.

608,320. Electric Combination Lock. Henry G. Carleton, New York City. Filed April 4, 1898.

608,321. Electric Lock. Henry G Carleton, New York City. Filed May 24, 1898.

608,322. Combination Mechanism for Electric Locks. Henry G. Carleton, New York City. Filed June 18, 1898.

608,343. Electric Heater. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company, same place. Filed April 6, 1895.

608,412. Joint for Electric Conductors. Herbert S. Patten, Montclair, and William Maver, Jr., Jersey City, N. J., assignors to themselves and Charles L. Heins, New York City. Filed Dec. 31, 1897.

608,415. Device for Recording and Reproducing Music. Ernest K. Adams, New York City. Filed March 26, 1897.

608,473. Apparatus for Preparing Cards for Use in Jacquard Machines. Robert G. McCrum, Armagh, Ireland. Filed June 2, 1897.

608,496. Coin-Controlled Medical Battery. Nelson M. Watson, Detroit, Mich. Filed Dec. 27, 1897.

608,537. Battery-Electrode. Henry E. Wilkinson, Mount Vernon, Ohio. Filed June 10, 1897.

TELEPHONE AND TELEGRAPH.

Two Bell Defeats.

Judge Hagner, at Washington, D. C., on the 4th inst., rendered a decision against the Chesapeake & Potomac Telephone Company in the first $50-rate case. The Judge granted James H. Manning a temporary injunction restraining the telephone company from taking its instrument from his place of business. Manning proffered the company a quarterly installment of rent under the $50 rate recently ordered by act of Congress. The company refused, demanded its old rental and threatened to take out its 'phone unless Manning paid up, and Judge Hagner held that the act of Congress was constitutional and that, pending future legal action, the company must furnish its service at the rate prescribed by the new law. The Manning case is but one of a score or more, and was made a test. The telephone company filed notice of an appeal.

Judge Showalter of the United States Circuit Court, Chicago, last week refused the injunction asked for by the Western Electric Company to prevent the Kellogg Switchboard & Supply Company from installing a switchboard for the Kinloch Telephone Company of St. Louis which the plaintiff claimed was an infringement. Judge Showalter denied the injunction on the broad ground that the Kinloch Company in St. Louis had spent over $1,000,000 already in fitting up its plant and that the company was engaged in a public service. He also ruled that the defendant, as a solvent corporation, would be able to answer to any damages if it should be proven later that they had infringed upon the plaintiff's alleged patent. The Judge, however, took occasion to declare that, in his opinion, there was nothing new in the Firman patent, on which the suit was based. Judge De Haven, of the United States Circuit Court for the Northern District of California, recently decided that the patent was valid, but the case was appealed to the United States Circuit Court of Appeals, where the defendant expects to reverse it. The Chicago decision means that the Kinloch Company will be able to go ahead with its switchboard work.

In Crawfordsville, Ind., a struggle for supremacy is being waged by the Central Union Company against the Harrison Telephone Company. The former uses the automatic system and has maintained a nominal plant in Crawfordsville for several years, with about a dozen subscribers. The Harrison system was put in about two years ago by local capitalists, and at once built up a large business. Lately the Central Company announced its intention of entering the field in earnest on a large scale. This at once engendered discord and the Harrison Company succeeded in inducing the council to annul the franchises of both companies and to grant them new ones, providing, among other things, a schedule of rates, the Harrison Company claiming that if the Central Union succeeded in freezing it out the rates would be inordinately raised. The Central Union refused to accept the new franchise, and declared that the council had no right to revoke its old franchise. An attempt to erect additional poles was made by the Central Union, when the Mayor stepped in and stopped the work, and the company has taken the matter to the courts.

A dispatch from Carlisle, Pa., states that the stockholders of the Cumberland Valley Telephone Company (recently incorporated with a capital stock of $50,000, ten per cent. of which is paid in) have named these new directors: D. K. Appenstellar, H. B. McNulty, Isaac Lesher, Dr. J. O. Skinner, E. M. Smith, W. L. Minnick, D. L. Grove, Chambersburg; John Zullinger, Orrstown; O. C. Gelwicks, St. Thomas. The board organized by electing D. K. Appenstellar president, Dr. J. O. Skinner vice-president, H. B. McNulty secretary, Dr. David McLay treasurer. Work will be commenced next month. The line will extend to all points in Franklin and Cumberland counties.

The Chicago "Inter Ocean" states that "the Chicago Telephone Company is considering the question of introducing the 'measured rate' system of charges. For some time the directors have been discussing the system, now in operation in Greater New York, Philadelphia, Boston and Buffalo, with a view to adopting it wholly or in a modified form in Chicago. At the same time some of the aldermen have been talking of presenting an ordinance to secure lower telephone rates for the small users. Superintendent Ellicott of the department of electricity has discussed the new plan with Comptroller Waller, and both agree that it would be a popular change in the company's methods of doing business."

J. A. Helvin, promoter of the new underground telephone system in Chattanooga, Tenn., is gratified over the interest found among the business people of the city in his undertaking. He has already secured several subscribers, and has received encouragement from everyone whom he has seen in regard to the new system.

A telephone system is to be established at Sycamore, O.

Independent Telephone Companies, Notice.

The recent decision in Pittsburg against the bridging telephones made by the Western Telephone Construction Company of Chicago has no bearing on the American Electric Telephone Company's bridging telephone; in fact, it leaves the American telephones about the only non-infringing multiple system in existence.

Moral: Do not rush into trouble. Buy American apparatus. AMERICAN ELECTRIC TELEPHONE CO.

The corporation attorney of St. Paul, Minn., has advised the committee on police of the council that the contract with the Northwestern Telephone Company, by which fifty-five telephones are furnished to the police department, can be terminated with thirty days' notice. Superintendent King has recommended that the telephones can be purchased at $5 each, while under the present arrangement with the telephone company the department pays an annual rental of $5 per year for each instrument.

I. L. Withers, W. D. Melton, J. P. Matthews, F. H. Weston and J. F. Livingston, the promoters of the new telephone exchange which it is purposed to establish in Columbia, S. C., are meeting with success in their canvass for subscribers. On the first day they secured over 100 signatures. Nothing will be done looking towards the building of a plant until 350 subscribers have been obtained. The promoters think they will have no trouble in getting that number.

It is said that the Government of Victoria, Australia, proposes to substitute iron and steel instead of wood for the 80,000 telegraph poles now erected in the colony. Provision for the first installment of 5,000 posts has already been made in the estimates for the next fiscal year.

The Phoenix Electric Telephone Company, of which George W. Sutton of New Rochelle is president, has applied to the trustees of Mamaroneck, N. Y., for a franchise to maintain a telephone line within the village limits. The company has already received a franchise in New Rochelle.

The Ripley Telephone Company of Ripley, Chautauqua county, N. Y., has been formed with a capital stock of $12,000. One of its principal directors and promoters is Assemblyman S. Frederick Nixon.

An effort is being made on the part of the town authorities of Pocomoke City, Md., to establish a complete telephone system, connecting Pocomoke with all the important towns on the Eastern Shore. Several have taken stock in the new enterprise, and the project is meeting with much success.

The Atchison Telephone Company of Atchison, Kan., a new concern, has elected the following officers: George Storch, president; J. T. Hersey, vice-president; S. A. Frazier, treasurer; E H. Berry, secretary. Mr. Berry will also manage the company.

The Colorado Telephone Company has begun service on its new toll line from Leadville to Granite via Twin Lakes. It is believed that later a line will be built between Canon City and Granite, thus giving Leadville another complete telephone line to Denver.

Manager Burt of the Missouri & Kansas Telephone Company announces that the line between St. Louis and Kansas City will be completed in from 30 to 60 days. The line when completed, will, he says, be as fine as any in the East.

The Bell Telephone instrument statement for the month ended July 20 shows: Gross output, 21,551; returned, 10,011; net output, 11 540. In the same month in 1897 the gross output was 15,859; returned, 7,241; net output, 8,618.

The Smithville, Tex., "Times" says that "an electrical supply firm of New York, through its State agents, is investigating the feasibility of putting in a telephone exchange in Smithville."

Since the change of administration in Portland, Ore., the Columbia 'phones have been taken out of all of the engine-houses in the city and the Oregon 'phones have been installed in their stead.

The village council of Alexandria, Minn., has granted the Alexandria Telephone Company the right to put in a telephone system.

Salida, Col., is to have a telephone system. The franchise has been secured and the work of setting poles and stringing wires will commence within ninety days.

A telephone exchange has been established at Albia, Ia.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 11⅜@11½c.; Lake, 11½c.; casting, 11¼@11½c.

The report of City Auditor Boyden makes the gross earnings of the Cincinnati Street Railway for the year 1897 $2,486,666.98.

The West Chicago Street Railway Company has declared a dividend of 1½ per cent., payable August 15 to stockholders of record August 5.

It is proposed to establish a $150,000 telephone company to operate in Worcester, Mass., in competition with the Bell Company. The stock will be offered for public subscription at $25 per share.

A company has been formed at Berlin, Ger., under the title of the Electric Power Company of Santiago de Chile, with a capital of 24,000,000 marks. Extensive electrical undertakings in Chile are soon to be started by the company.

Trains of the Lexington Avenue line of the Brooklyn (N. Y.) Elevated Railroad have begun running over the Brooklyn Bridge permanently. They are to run on three-minute headway, and are operated by motor cars, with the third rail system, from the Bridge street station, Brooklyn.

A Boston dispatch states that the directors of the Electrolytic Marine Salts Company are still hopeful that the stockholders will get about 30 per cent. of the par value of the stock if litigation in the courts does not follow and a receiver is appointed. If such a thing takes place, the directors argue that about all the money in their possession will be used up in legal expenses, and that the stockholders would scarcely have anything left.

The United States Commissioner to the Paris Exposition has opened offices in the Equitable Building, New York. The office in New York will be in charge of an Assistant Commissioner-General and will cover the Eastern States, while a similar office in Chicago will cover the West. Chief Commissioner Ferdinand W. Peck will go next month to Paris, where he hopes to get more space for this country. It will probably be suggested to American exhibitors that they combine their exhibits, as otherwise many would have to go unrepresented.

Papers for the merging of the Nassau Electric Railway with the Kings County Electric Railway Company, the Coney Island, Fort Hamilton & Brooklyn Railroad and the Union Railroad Company were filed in Brooklyn, N. Y., on the 3d inst. The capital stock of the Nassau Company is increased from $6,000,000 to $15,000,000, divided into $6,500,000 cumulative 4 per cent. preferred and $8,500,000 common stock. The liabilities of the Nassau Company are stated as $5,500,000 in 5 per cent. mortgage bonds, a floating indebtedness of $1,811,200 and $480,000 permanent annual rental charges.

The Governor and Attorney-General of New Jersey on the 2d inst. accepted a check for $11,500 from the Electro Pneumatic Company, whose charter was declared void by Governor Griggs last year for non-payment of franchise taxes amounting to $18,000. The company has been reinstated as a New Jersey corporation under authority given to the Governor and Attorney-General by the last Legislature. It was incorporated in 1886 to make and use pneumatic and electrical inventions for the distribution of packages.

The space regulation in the operation of trolley cars on the Brooklyn Bridge has materially reduced the number of cars that can be operated during rush hours and has therefore diminished the receipts of the trolley companies. A number of plans to overcome the difficulty are being considered. Engineers who have closely examined the bridge structure say there is no danger to be feared from any load that traffic on it is likely to cause. Bridge Commissioner Shea, however, has invited Washington A. Roebling to come to New York and make an examination of the bridge, his report to be furnished to the general public as speedily as possible, in order that they may have authoritative information regarding the present condition of the structure.

W. Huntington, president of the American Railway Electric Light Company, has demanded of the Philadelphia "News Bureau" from whom it secured its information regarding an article it published lately, in which it was stated that a receivership for the company was not improbable in order to effect a reorganization. The letter continues: "You must be aware of the fact that the publication of such a notice, which in its effect depreciates the value of the holdings of a large number of stockholders and which notice is unwarranted by facts and unjustified in the nature of its insinuations, is, according to law, an indictable offence." Mr. Huntington says that unless the information sought is given he will proceed against the "News Bureau."

The Cleveland Electric Illuminating Company's first mortgage 5 per cent. gold bonds are recommended by Spencer Trask & Co. as being particularly desirable for permanent investment. The bonds are in coupon form, $1,000 each, with privilege of registration. They are redeemable on and after April 1, 1910, at 110 and accrued interest. The amount outstanding is $1,200,000. These bonds are secured by a first mortgage on all the property, rights and franchises of the Cleveland Electric Illuminating Company, which is the only electric lighting company in the city of Cleveland, O.

According to the "American Manufacturer," electricity is furnished near Niagara Falls for $18 per horse-power per year for continuous service. Allowing a loss in the application of 25 per cent. in the case of electricity and 50 per cent. in the case of steam, due to the greater use of belting and shafting, the mill using 1,000 horse-power under steam conditions would need only 750 electrical horse-power. This, at $18, amounts to only $13,500, against $60,000 for the steam plant, or a saving of $46,500 per year. This sum represents a dividend of nearly 10 per cent. on a capital of $500,000.

The Chicago "News" says: "The Commonwealth Electric Company will issue $2,500,000 5 per cent. 45-year bonds. A syndicate is forming which will take $2,000,000 (the amount that will be put out at once) of the security. There will also be reserved $150,000 to take up a like amount of underlying bonds issued by the various corporations which were absorbed by the Commonwealth, and the remaining $350,000 of bonds will be issuable for extensions. The mortgage will provide that after this $2,500,000 of bonds are issued still other bonds may be issued to cover 75 per cent. of the actual cost of further extensions and improvements."

The industrial and commercial development of electricity on a large scale dates practically from the International Electric Exhibition held in Philadelphia in 1884. At that time the total investment in electrical applications in the United States, exclusive of telegraphy and telephony, was less than $1,000,000. The capitalization in the electrical applications in this country at the present time is estimated at about $1,900,000,000. The electric lighting plants in the United States represent a money investment of $600,000,000. Electric railways have a mileage of 14,000, with a nominal capitalization of about $1,000,000,000, and employ 175,000 men. The capitalization of the telephone service is about $100,000,000, and about 1,000,000 telephones are in daily use.

The Boston "News Bureau" says: "The proposed reorganization of the American Electric Heating Corporation whereby the $10,000,000 capital was to be scaled to $1,000,000 will probably not be attempted this year. The bondholders of the company are also the largest stockholders and they will probably be content to go without their interest and effect no radical reorganization at present, in the hope of better things to come. The large owners of this company believe that there are great possibilities in the electric heating field, but they realize that electric heating is in its infancy, and it is not anticipated that the use of electric heating apparatus will come into general use until lower rates are obtainable for electricity."

ELECTRICITY.

Vol. XV. NEW YORK, AUGUST 17, 1898. No. 6.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4081 Cortlandt.

SUBSCRIPTION RATES:

United States,	$2.50
In Clubs of Five or More,	2.00
Foreign Countries,	4.50
Single Copies,	10 cents

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

The General Electric Company and its Impaired Capital.

At the special meeting of the stockholders of the General Electric Company at Schenectady on August 10, for the purpose of reducing its capital stock, over 95 per cent. of the shares of the stock was represented. Such a large number of proxies were handed in however that the whole of the afternoon was consumed in checking them off. It was 6 o'clock before the credential committee, which consisted of Messrs. W. Lowell Putnam, R. Treat Paine and M. F. Westover, was ready to report, and it was therefore decided to defer voting on the question until August 17.

Mr. Putnam presented a minority report, objecting on various grounds to some of the proxies. The majority report on the other hand approved of the authority of all the proxies presented, both reports being finally ordered filed.

A question was raised as to the legality of the action taken, the counsel of the company giving it as his opinion that no injunction would be granted upon the bill of complaint by Mr. T. L. Livermore, and that, even granting action should be taken, it would merely place the stockholders back to their original rating. Mr. Livermore claims that the proposed reduction will be injurious to the interests of the minority holding preferred stock, and also that the common stock is not properly represented, while those in favor of the plan assert that with the capital reduced the stockholders will be able to draw dividends, and that furthermore it would be of great benefit to the company.

That some action looking toward a reorganization was necessary has long been apparent to all those in any way familiar with the financial condition of the General Electric Company, especially during the last few years. According to its Sixth Annual Report the company's net earnings during last year amounted to $1,231,852.37, while it owes its preferred stockholders $1,488,200 unpaid dividends that have been accumulating since July, 1893. In other words, it would take more than a year's net earnings to settle with its preferred stockholders, to say nothing of its common stock, on which likewise no dividends have been paid for the last five years. All the accumulated unpaid dividends on the preferred should by right have been added to the liabilities of the General Electric Company and considered as such, but, as we have frequently pointed out, as liabilities they have been persistently ignored.

This proposed reduction of preferred stock, and likewise of future dividends, by a joint vote of the preferred and common stockholders, would seem in our opinion to be a very dangerous precedent, for if such action is allowed to pass what is to prevent a corporation in which, as is usually the case, the common stockholders are in the majority from voting, if it feels so inclined, to reduce the holdings of the preferred stockholder ninety, or for that matter even 100, per cent. and thus get rid of him altogether? This method of remedying capital impairment should have the effect of making purchasers of preferred stock extremely cautious.

If the proposed deal goes through, and the preferred stockholders are paid their accumulated dividends, and the value of patents is reduced by $4,000,000, the next Annual Report of the General Electric Company will cut but a sorry figure.

* * *

Motive Power on Elevated and Suburban Roads.

The question of adopting a suitable motive power on street railways, elevated and suburban roads is an all-important one. The Metropolitan Street Railway Company of New York has just issued some $15,000,000 in bonds for the alleged purpose of equipping its remaining lines with electricity, and there is still much talk of changing the motive power on the elevated roads, although the policy of the Manhattan Elevated people would seem to be that of making haste slowly. In a very interesting article on this subject which recently appeared in the New York *Times*, Mr. H. G. Prout says:

"Whether or not electricity would save anything in cost of operation in this special case is a matter of debate among experts. The steam locomotives now used on the Manhattan Elevated are efficient machines, and, taken all in all, the elevated railroads of New York give the people a service which in the combination of the magnitude of the traffic, the safety with which it is carried, the speed, the regularity, the comfort, and the economy is unparalleled in the history of transportation; it is probable that no other instance can be found in which these elements are combined on such a scale. But, further, the service is possibly the most intense in the world, and an interruption causes inconvenience to thousands of people. But with the steam locomotive each train is a self-contained unit, and an accident to that train does not necessarily interrupt the traffic over the whole line or interrupt it for a considerable time, but with electric working the whole system is on one string. A failure in the power house or in the conductors stops everything. In practice this difficulty is not as serious as it is in theory, but the danger is present, and the prudent engineer is bound to think of it when he decides between steam and electricity."

In the last half of the above paragraph the writer

aptly points out the principal disadvantage attending the use of electricity either on an elevated road or on roads such as the electrically equipped sections of the New York, New Haven & Hartford Railroad. That there would be danger of a suburban road equipped electrically breaking down at some inopportune moment is not to be doubted, and for this reason the equipping of such a road with, for instance, the third-rail system would scarcely seem advisable. Imagine the inconvenience that would be experienced were a suburban road such as the Long Island Railroad to break down on a summer morning as occasionally happens in the case of the Brooklyn Bridge cars. In regard to the equipping of the Manhattan Elevated with electricity, the advantages to be gained by doing away with the existing smoke nuisance and affording increased traffic would in our opinion outweigh the danger of a breakdown occurring, and even in the event of a breakdown there are other means in a city such as New York for speedily reaching one's destination.

* * *

Electricity in Mines. Until recently compressed air or steam was the motive power most generally adopted in mines. During the last few years, however, electricity has been gradually made use of for various mining purposes, first being installed in what are termed non-fiery mines or collieries in which explosive gases do not accumulate. The purposes for which power in most mines is required are haulage, drilling, coal cutting, pumping, hoisting, lighting, signaling and blast firing. The introduction of electric haulage in non-fiery mines offers no serious difficulty and has been adopted in a number of cases, as the cost of haulage by electricity is some thirty per cent. less than with mules. The electric drill, of which there are two distinct types, is also coming more and more into use, especially in coal mining. For the latter class of work, or where soft rock is to be pierced, what is known as the augur-drill is used. This type of drill is mounted upon an iron frame which is held upright by being securely pressed between an overhead beam and the floor by means of a vertical screw at the bottom much resembling in appearance and operation the old form of jackscrew. An electric motor is securely fastened to the frame, a pinion being attached to the armature shaft, which in turn gears in a toothed wheel of larger diameter, through which the augur passes. The necessary current for operating a drill of this description may either be taken directly from the mains or from a generator mounted upon a car. When boring through coal, holes may be drilled at the rate of a foot a minute, which has proven considerably more economical than hand work, in spite of the fact that the whole apparatus has frequently to be taken down and moved to a new spot, entailing considerable time and labor.

The electrical percussion-drill is operated on an entirely different principle from the augur drill, a plunger to which the drill is attached being made to move through the medium of magnets backwards and forwards in a cylinder somewhat similar to that of a locomotive.

Electric coal-cutters are now quite extensively employed in mines in various parts of this country. Their principal advantage would seem to lie in the fact that where such a machine is used the coal can be gotten out with much less breakage and consequent waste. Statistics go to show that a man working with an electric coal-cutting machine can under ordinary circumstances get out one-third more coal than can a man working with a pick. This does not necessarily mean that there is one-third more profit in the use of such a machine than by the hand method, as the cost of the current, repairs and interest on the outlay would have to be deducted; but even allowing liberally for these items the electric coal cutter has proven more economical.

As far as hoisting by electricity is concerned, the constant starting and stopping is not conducive to economy as the motor is essentially a constant-speed machine if high efficiency is required. In spite of this fact, however, in mines that are equipped with electricity electric hoists are used to a limited extent. The firing of blasts is usually accomplished by small portable machines and not as a rule by taking current from the electrical mains.

Great care has to be exercised in installing electrical apparatus in fiery mines, and until comparatively recently the motive power in such mines has been compressed air. All wires, switches and motors have to be arranged in such a manner as to eliminate all possibility of sparking. However, since the introduction of polyphase motors, requiring no commutators or brushes, the problem has been simplified, and by observing proper precaution in running the wires and placing the other apparatus, little danger from explosion due to an electric spark is to be apprehended.

That electricity will gradually supersede other forms of power in mines cannot be doubted. Mr. Rankin Kennedy, who a few years ago thoroughly investigated the advantages and disadvantages of electricity in mines, expressed his opinion in one of the leading English technical papers as follows: "In the non-fiery mines electrical transmission is cheaper in first cost and in maintenance, much easier applied and higher in efficiency than compressed air. In fiery mines it is much more efficient and with induction motors quite as safe, although difference in first cost is not so great."

Under the Searchlight.

Notes and Comments on Various Topics.

More Financial Jugglery.

The Boston *News Bureau* of August 11 says:

It is officially stated that the directors of the Westinghouse Electric & Manufacturing Company have, by authorizing the issue of $3,500,000 fifteen-year 5 per cent. gold debenture certificates and by selling $3,000,000 of such issue, completed a financial transaction of great advantage to the company and its stockholders. The proceeds of the sale of these debentures will retire the outstanding floating and bonded debts of the company and return to its treasury as available assets stocks and bonds in various lighting and power companies yielding an annual income exceeding one-half the interest charges of the debenture certificates.

Where have these bonds been—in hock? The common stock of the Westinghouse Company having lately been worked up some five or six points, it would seem as though Mr. Westinghouse contemplated following in the footsteps of Mr. Coffin. It would however be shockingly rough on the creditors of the Westinghouse Company were the preferred stock of that corporation reduced by vote of the common shareholders.

* * *

"LIGHTNING" of London is responsible for the following:

A few days ago I was riding on an electric tramcar, and, contrary to all regulations, fell into conversation with the man at the wheel. After hearing to my astonishment that he had learned the profession of "motorman" in thirty minutes, I mildly suggested that he should teach me. He evidently thought this would be too much for him, but after a little polite persuasion, and the signature of an affidavit that I considered myself to be a sober and devout individual of sound mind and well disposed towards the commonweal, he put me on to the handles. Now driving a tramcar is like riding a bicycle, quite easy when you are used to it but at first you are apt to get mixed. All went smoothly for a few seconds; we were bowling down hill with no current on and there was a sharp curve in front. "Slow down and ring the bell," said my tutor, so I put on the brake. "Where's the bell?" says I. "Down below," says he. Looking down I observed a lever sticking out, something like the knee swell of an organ, so I knocked it over and the bell rang; then away we went again, my tutor instructing me in real Thames steamboat fashion—"Ease her," "Stop her," "Start her," "Turn astarn," etc. Then, as we overhaul a perambulator, "Ring bell," says he, so down I come on the knee swell. "That's the sand box," says he; but the baby saw the tram and screamed, and the nurse cleared out, kissing her hand to the conductor—so we were all saved. My tutor thought I did pretty well for a beginner, so I handed him the reins and lit a cigar. On the whole, I conclude he was better pleased with my smoking than my driving; of course something must be allowed for experience.

* * *

BY the terms of the protocol signed by the representatives of the United States and Spain at Washington on the 12th inst., Spain relinquishes all claim of sovereignty over and title to Cuba; Porto Rico and other Spanish islands in the West Indies, and an island in the Ladrones, to be selected, are ceded to the United States, and the United States will hold and occupy the bay and harbor of Manila pending the conclusion of a treaty of peace which shall determine the control, disposition and government of the Philippines. These are the results of the war between Spain and the United States in the year of our Lord 1898, of which the following is a skeleton chronological record:

Feb. 15—The battleship Maine blown up in Havana harbor.
May 1—Dewey destroys Spanish fleet at Manila.
May 19—Cervera's fleet reaches Santiago.
June 3—Sinking of the Merrimac.
June 22—Shafter's army lands at Baiquiri.
June 26 to July 4—A series of brilliant engagements on the outskirts of Santiago including the capture of El Caney and storming the heights of San Juan.
July 3—Cervera's fleet destroyed.
July 14—Santiago surrenders.
July 26—Miles lands at Guanica.
July 29—Ponce surrenders.
Aug. 11—Spain accepts our peace terms.

To this may be added the capture of Manila by Dewey on August 13.

THE Boston *News Bureau* is responsible for the following:

One prominently identified with electrical matters says: "I do not believe that many of the manufacturers of electrical machinery, such as the General Electric, Westinghouse and Walker companies, are making money to-day notwithstanding the fact that they are all rushed with orders. The reason for this is that they are obliged to do so much experimental work that a goodly percentage of profits goes into the scrap heap. Many contracts are taken at prices which show a loss, principally for the reason that the company's experts find it impossible to give reliable estimates on machinery which the companies have never before manufactured. I believe that a general electrical consolidation will have to take place before there will be any large profits in the business, for with three or four competing companies in the field, all with large salary lists, prices are bound to be placed as low as to prove unprofitable to the companies securing the contracts."

There is not the slightest doubt but what some of the larger electrical manufacturing concerns, notably the General Electric Company, are in the habit of taking contracts at an extremely low figure, with little or no profit, but we do not think that this is due to any of the reasons given above. There are other reasons for this, and we have frequently pointed them out.

* * *

WE reproduce the following from the New York *World*, and sincerely trust none of our readers will laugh themselves ill:

He—Have you heard the latest?
She—What is it?
He—Never look an auto-car in the motor.

* * *

THE American officers in Santiago are laughing over a joke which some of the Spanish officers told on themselves. At the Casino Espanol they had a graphophone and during the siege the favorite piece of music which came from the instrument was one of whose name and origin they were ignorant. It was not until after the capitulation of the city that they learned from American bands that their favorite tune was "The Star Spangled Banner."

* * *

COMMISSIONER OF INTERNAL REVENUE SCOTT has announced that the Internal Revenue office holds that

an electric belt, manufactured and recommended as a remedy for diseases of the human body, is a mechanical appliance or device, and although used remedially or medicinally, cannot properly be included in the terms of Schedule B of the War Revenue Act taxing medicinal preparations. This decision would certainly seem just, as the so-called electric belt is unquestionably purely a mechanical appliance and should not be taxed as a remedy any more than the faith cure.

* * *

The barbed-wire fences surrounding Santiago, and which have proven a hindrance and nuisance to our hard-worked soldiers, have, it seems, after all, their advantages. Not long ago one of the wires of such a fence was sufficiently insulated to allow of telegraphic messages being sent from one army corps to another a distance of five miles. Thus the Spaniards unwittingly saved the enemy's signal corps the trouble of laying a wire through a rugged country.

* * *

Probably the first practical application of wireless telegraphy took place during the Royal Alfred Yacht Club Regatta held recently in English waters. Wireless messages describing the race were sent over distances varying from five to ten miles, and were published in successive editions of the Dublin *Evening Mail*. Signor Marconi was himself the operator, transmitting the messages from a steam tug, "The Flying Huntress." The instruments are said to have worked splendidly and not a single message had to be repeated.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

"FOOLS ARE MY THEME."

It is a creed with some that the fools far outnumber the wise in this world. We have never ourselves advanced this doctrine, but there are times when we are impelled to ask if it does not contain an element of truth. Otherwise how can we explain the present situation of the Electrolytic Marine Salts Company? To be quite frank, we had not supposed the fools to be anywhere near so plentiful as the experience of this company has demonstrated; and that perhaps is saying a good deal. When the Reverend Jernegan and his associates began to send out their circulars inviting the public to subscribe to their little scheme to extract gold from sea water, we expected they would "rake in" some money before they fled the country, but we did not anticipate that they would "go through" so many persons of presumed business intelligence. The masses, being without financial training, are peculiarly liable to be taken in by every trickster that comes along. But when a man has been in business thirty or forty years, and has displayed enough judgment to acquire a competency, you have a right to expect that he will not try to extract sunshine from cucumbers or gold from sea water. The fact that so many persons of large means were caught by such a palpable fraud as the Electrolytic Marine Salts Company is calculated to make cynics the world over laugh themselves hoarse.

We suspect it will be necessary to go back nearly two hundred years to find an enterprise on its face so delightfully absurd as the Electrolytic Marine Salts Company. Many comments are now being passed on the Reverend Jernegan's shrewdness, but we are inclined to believe that were he not by nature a most consummate ass he would never have attempted such a scheme. It is incredible that any one in his senses should have believed that there was the ghost of a possibility of "working the racket." And yet it worked beautifully, and perhaps after all its promoter was endowed with a knowledge of human nature so profound as to be almost preternatural. He certainly sized-up his fellow-creatures much more accurately than we should have done, and we do not mind confessing that this is an acknowledgment we do not consider due everyone.

Well, the gentlemen who have put their $10,000 apiece into the Electrolytic Marine Salts Company—to say nothing of the humbler contributors—may now consider that their money has "suffered a sea change into something rich and strange." They have our sympathy, but we can, nevertheless, not help drawing the comforting reflection that life will never become "flat, stale and unprofitable" (though we are not so sure in the latter particular) while such delightful rogues as Jernegan abound.

We always feel inclined after an episode like this to give some good advice. Our first point is, beware of enterprises that are floated on the names of clergymen. We regard the clerical profession the highest among men, but we have not much regard for clergymen who descend from that lofty estate to float joint stock companies. And if we may be quite frank, we may say that we regard as a fool any man who views the situation differently. In the second place, scrutinize sharply every kind of a stock that is offered you at fifty cents a share. A small par value does not always indicate bad faith or poor prospects, but when you consider that the proportion of companies so capitalized that go to the wall is overwhelmingly large, it is just as well to look before you leap. In the third place, use a little of the reason with which you have been endowed by nature, and reject all schemes which on their face are absurd. But it may be said that the Electrolytic Marine Salts Company was not of such. Well, we have no reply to make, except perhaps to say that the person so holding has our entire sympathy. One is not to be blamed for congenital defects.—*U. S. Investor.*

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS.

The Annual Convention of the above Association was held at Elmira, N. Y., on the 10th and 11th inst. About sixty delegates were in attendance and many of them were accompanied by their wives and daughters. The acting mayor of the city, Alderman A. J. Watson, welcomed the visitors to the city in a brief but hearty speech, which was appropriately responded to by Clarence E. Stump. President William Y. Ellet of the Association then delivered an address in which he said:

"Our work is not a mere trade. We do not hold a job. By faithful study and by practical demonstration we are fast raising our business into the grade of a profession. It is now taught in the progressive colleges and a start may be made towards acquiring its mastery while still under pupilage in the schools. It follows that there is something of permanency in the position of municipal electrician when once it has been attained; and this is wise, for the expert has not only to know his apparatus, but must also know how and where every portion of it is located throughout the city which he guards; and this is not the least of his requirements. Other men will honor us as electricians if we but honor the profession that we pursue. The progress of electrical science is the wonder of this wonderful age. The men who keep abreast of its development are in the forefront of progress; the world is looking to electrical experts for its freshest triumphs, and they are invading as well as transforming every field of human industry. If we bear a modest part in this great advance it is still an important one and is never at a standstill. The discussions of this meeting will amply demonstrate this proposition. The able men who adorn the roll of our membership will find a hearing far beyond the walls of this chamber, and in the secular as well as in the technical press."

The papers read were as follows:

"Electrolysis; the Best Means of Prevention," by Capt. Wm. Brophy of Boston, Mass.

"Maintenance of Central Office, embracing the Storage Battery," by Morris W. Mead of Pittsburg, Pa.

"Aerial Construction," by W. H. Thompson of Richmond, Va.

"The Difficulties a Superintendent Has to Contend With, and the Best Way to Avoid Them," by F. P. Foster of Corning, N. Y.

"What the Association Has Accomplished Since Organization," by J. W. Aydon of Wilmington, Del.

Wilmington, Del., was selected for the next Annual Convention. The officers elected will be found in our "Telephone and Telegraph" department. The name of the Association there given, however, is "The National Fire & Police Telegraph Superintendents and City Electricians' Association."

The new president, J. W. Aydon, was born in Wilmington in 1850. He learned telegraphy in the office of the Western Union Telegraph Company in Philadelphia, and entered the service of the Philadelphia, Wilmington & Baltimore Railroad Company in May, 1868, as operator at Clayton, Del.; in 1871 was appointed train dispatcher in the Philadelphia office. He is now completing his thirtieth year of continuous service for that company, many years of which have been spent in the Wilmington office. Mr. Aydon has always taken an active part and shown a deep interest in public affairs, and in 1883 he was elected superintendent of the police and fire alarm systems of Wilmington, which position, with a slight intermission, he has held since.

M. WITZ ON THE DIESEL MOTOR.

Writing in the *Revue Général des Sciences*, that well-known authority on the gas engine, M. Aimé Witz, criticizes the Diesel motor and explains it. He shows first how the Carnot cycle, which gives a maximum efficiency, commences with an isothermal compression, continues the compression adiabatically, commences the expansion isothermally and continues it to the initial point adiabatically. But to secure an ignition temperature from the adiabatic portion of the compression it would be necessary to use a pressure which would be inadmissibly high in practice. M. Diesel therefore abandoned the double compression and replaced it by a single adiabatic compression whereby he attains the temperature of ignition. He then introduces fuel and allows expansion to proceed along an isothermal until the fuel entry being cut off the remainder of the expansion takes place adiabatically. The effect is not equal to that of the Carnot cycle; it is less though still high. For a pressure of 250 atmospheres the efficiency is 0.730. Good as this is, the ordinary gas engine would give an equal return for equal compression and possesses all the advantages in elasticity and power, complete combustion and smartness of running that is possessed by the Diesel motor. In a word, the Diesel motor has no theoretic pre-eminence over the ordinary combustion motors.

Though M. Diesel contemplates air compression to 250 atmospheres and the employment of solid fuel pulverized, in reality the engine set to work in summer, 1897, had only 35 atmospheres of compression and used petroleum in one cylinder in place of the three cylinders contemplated in the compound ideal engine. The theoretic cycle is cut short at each end of the diagram, and the cycle is as follows: (1) Indraft of air during the descent of the piston; (2) compression of this air on the up stroke; (3) introduction of combustible gradually, and expansion along the double curve, first isothermally, and then, after cut-off, adiabatically; (4) exhaust.

There is a small air compressing pump which delivers to a reservoir; distribution is effected by

valves actuated by cams. The valves are in no sense peculiar, but are very carefully made for the high pressures employed of 35 atmospheres, M. Diesel having however renounced his ideas as to 250 atmospheres. Injection of combustible is regulated as to its duration of injection by means of a centrifugal governor. Though Diesel has not been able to realize his expectations, his motor may be considered worthy of attention. The substitution of a practical cyle of maximum efficiency for the Carnot cycle has vanished, and the actual motor is less original than the idea which gave it birth, but the cycle realized is sufficiently interesting to constitute a distinct event in the history of the oil motor industry. The existing motor, as made, has a power of about 20 HP., a cylinder of 0m.250 in diameter and 0m.40 stroke. It makes about 160 revolutions per minute and consumes 230 grammes of oil per HP. hour effective (? brake) at full power, and 278 grammes at half power, a remarkable result comparable with the Priestman 8 HP. engine at the Plymouth trials, which consumed 385 grammes; the Niel motor at Meaux of 6 HP., which used 307 grammes, and the Grob motor of 7 HP., which used 271 grammes. A 4 HP. motor of one Pétréano was claimed to have only used 250 grammes. Thus the Diesel motor is allowed by M. Witz to be the first in economy. The calorific power of petroleum being 11.015 calories, the horse-power hour requires 2.621 calories. The efficiency is thus 24.2 per cent. as against the best at Meaux of 21.2 per cent. M. Witz expects that Diesel may even improve on these results, and recommends inventors to follow his example and strive after higher compression, a fact pointed out long enough since.—*Electrical Review, London.*

FALK CAST-WELDED RAIL JOINTS AT NORWICH AND COVENTRY.

As announced by us a short time ago, the Falk system of cast-welding has been adopted for the Norwich and Coventry electric tramways. The essential difference between tramway and railway track is that the rails for a tramway when once laid are covered in up to the tread of the rail by paving of some sort, while railway rails are exposed. When tramway track is once laid, unless special devices are adopted, it is impossible to get at the fishplates, and the bolts become loose. It has been the experience on all the tramways in this country on which mechanical power has been used, that after a very few years the joints begin to give trouble. When heavy motor cars pass over a joint, unless the joint is absolutely solid, there is a tendency on the part of the rails to separate while the wheel is passing from one rail on to the other. This causes what is known as the "hammer-blow," which is both injurious to the motors on the car and bad for the track. It causes the head of the rail to wear down at joints, thus increasing the tendency to hammer. The best possible track would be a continuous one, i. e., without any joints whatsoever. For many years past, but especially since electric traction was introduced, means have been sought whereby this could be practically attained. The first idea naturally was to electrically weld the rails, and the Johnson Company of the United States spent a great deal of time and money in trying to perfect a system of electrically welding the track. As far as the operation itself went, it was perfectly successful. There was only one drawback, namely, the cost of the plant required to do the work, and the necessity of having highly skilled labor. The price of the joint was therefore excessive.

The Falk Manufacturing Company finally succeeded in practically solving this problem, and since 1894 a very large mileage of track in the United States has been laid on their system, and excellent results have been obtained. We have examined many miles of such track, and have found this method of jointing give very excellent results in practice. There is still in this country a great prejudice against the continuous rail. It is thought by some that if a continuous track is laid, and the paving on the length of road removed, the track will buckle or "hog," but experience has proved that this is not the case. In tramway work variations of temperature do not affect the rails as much as one might expect, owing to their being entirely covered in and supported by pavement. It is easy to ascertain the strain on the rails due to the variations of temperature. Assuming a coefficient of expansion for steel of 0.0000065, and multiplying this by 75, which is a liberal figure for the number of degrees of maximum deviation from the temperature at which the welding is done, we get 0.000487, which is that part of its length which a rail would vary when exposed to a variation of 75 degrees. A steel bar will extend 0.00003 of its length when subjected to a tensile stress of 1,000 lb. per square inch. Dividing the estimated expansion by this figure, we get for the strain 16,200 lb. per square inch, as that due to 75 degrees if no expansion is permitted. As 40,000 lb. per square inch is a safe value for the elastic limit of steel, it can readily be seen that the elastic limit is not reached.

Wherever joints have broken, in no case have they pulled apart more than 2 in. This would seem to show that the pull which broke the joint was not a cumulative effort extending all along the line, but merely the result of a local strain extending but a short distance on either side of the joint.

The Falk system is now being introduced into this country for the first time by Mr. Robert W. Blackwell, at Coventry and at Norwich, where some 5,000 joints are now being cast-welded. The system roughly consists in casting a cast-iron sleeve round the sides and bottom of the rail joints, the rail ends being first placed firmly together. In cases where they do not absolutely touch, thin plates of steel are driven in between the heads of the rails before casting. Before fixing the molds, which are of cast iron, the sides and bottom of the rail are cleaned, and this is generally done with an emery wheel or a sand blast. The cast iron used is of a special mixture found to give the best results, and it is run at a greater heat than is used in making ordinary castings. The cast iron running into the iron molds chills rapidly on the outside surface, thus causing very great pressure to be exerted on the metal which is still in its molten state in contact with the web and foot of the rail. As the metal is poured in from one side and comes in contact with the web or thinnest part of the rail at its greatest heat, this part of the rail is brought to a white heat, and owing to the pressure exerted on the molten cast iron, this is practically forced into the interstices of the steel, thus not only making a thoroughly good mechanical joint, but also ensuring a good electrical bond. The section of the cast-iron joint is so designed as to have at least the same tensile strength as that possessed by the rail. The cast-welded joints used are generally about 14 in. long, and the weight of cast iron varies in accordance with the weight of the rail from 70 lb. to 140 lb. per joint.

The cast iron must necessarily be melted close to where the work is being done, and for this purpose a portable cupola on wheels is necessary. The welding plant used at Coventry consists of a small cupola with the necessary fan, steam turbine and boiler fitted on to a truck to be drawn by horses. In the plant used at Norwich gearing is fixed to the wheels, so that the steam engine which drives the fan is also utilized to propel the car.

In answer to the various *a priori* objections which have been raised against the principle of cast-welding, it may be stated, as one example among many, that in 10 miles of track which were cast-welded at St. Louis in the early part of 1894 and over which there has been a very heavy traffic, the joints to-day are in as good condition as when they were first made, and so perfect that it is practically impossible to detect them. At the present moment there are some 200,000 cast joints in the United States, while a large amount of cast-welding has been done in France and Germany.—*Electrician, London.*

Wind as a Motive Power.

The well-known Danish scientist and inventor, Prof. La Cour, has given the question of a more rational utilization of the wind's power a most thorough and careful attention for a series of years, and has carried on a number of State-aided experiments and tests in this connection. In an interesting lecture before a Copenhagen scientific society, Prof. La Cour recently communicated some of the results he had already obtained. He first touched upon a few historical points, stating that the first epoch-making technical essay had emanated from the Alexandrine mathematician, Hero, who lived some 2,000 years ago. The matter was allowed to rest for 1,500 years, when a new move was made in the Orient and by the Mohamedans carried to Europe, where it grew and increased until it, by the discovery of the application of steam, received an immense impetus. But Hero's essay had given the first impulse; it was widely translated and commented upon. The utilization of wind-power became more general, and the engineers of that period gave the bulk of their attention to the construction of wind and water mills. With regard to the most practical construction of a wind mill, says the *Engineering* (London), Prof. La Cour pointed out the fallacy of the opinion that the greatest effect was obtained by horizontally-moving wings. He touched upon he various manners in which the problem of turning the mill according to the wind had been solved, and then dealt with the construction of the wings. The great mathematicians of the last century had given much attention to this question, but all their careful calculations had not led to any real results. Their physical suppositions were erroneous, because they held that the effect upon the mill exclusively depended upon the pressure of the wind when it struck the wings.

The question of the effect of the wind's pressure upon a flat surface is a complicated one, but it has in any case been demonstrated that the suction on the leeside is a very important factor. Prof. La Cour had at his experiments measured the effect an artificial—and consequently even—wind had upon different models at different speeds, and these experiments bore out the correctness of some of the ordinarily accepted rules in the construction of windmills, for instance, as regards the number of wings. A mill with 16 wings has only $1\frac{1}{3}$ times as much power as one with four. In measuring the percentage of the power of the wind striking the wings which was absorbed or utilized by the latter he arrived at the, at first sight, somewhat startling figure of 143.7 per cent. This unlooked-for result was owing to the above-mentioned suction on the lee side of the wind passing between the wings. That the wings should not be plane, but have a bent or a concave shape, was an old-established truism, and the shape of the wings has in reality much influence upon the suction which is more especially caused by the wind which just passes the edges of the wing.

In measuring the percentage of the wind-power utilized it was, consequently, also taken into account the wind passing between the wings, and, instead of 143.7 per cent., the figure was 21 per cent. The absolutely best shape for wings has, however, not yet been ascertained. The most important practical point in connection with windmills is the solution of the problem how best to neutralize the inconveniences caused by the irregularity of the wind. Prof. La Cour has for this purpose constructed an original regulator, called the kratostate, by means of which a windmill can very well be used for working a dynamo.

THE USE OF ACCUMULATORS IN CONNECTION WITH LIGHTING AND TRACTION SYSTEMS.*

BY JOHN H. RIDER,

Borough Electrical Engineer, Plymouth, Eng.

Accumulators have always been an essential part of the equipment of a continuous current lighting station and their value is becoming more recognized every day in alternating current and power stations. In order, therefore, that the opinions and experiences of members may be obtained, this paper is presented, with the hope that it may give rise to a useful discussion.

The efficiency of accumulators $\frac{\text{watts output}}{\text{watts input}}$ will seldom exceed 75 per cent. under ordinary working conditions, and since a steam plant must always be used to charge them, it follows that a given output can generally be obtained more cheaply directly from the steam plant, if it can be run at an economical load, than from accumulators.

But in deciding what is an economical load for any given set of steam plant, the whole of the plant—boilers and piping, as well as engines and dynamos—must be taken into account. By proper subdivision of the dynamo units, it will generally be found possible to keep the running sets at a fairly economical load. But with the boilers and piping it is different. Steam has practically to be kept up for the whole of the 24 hours in as many boilers as will be required at the maximum load, and the whole of the steam piping kept connected ready for use. So that at, say, anything under three-quarters of the maximum load, the steam plant is generally working uneconomically, because of the large "standby" and radiating losses. Therefore it would pay to run one of the dynamos, if necessary, for the sole purpose of charging accumulators when the load on the plant as a whole had dropped to an uneconomical point. Or if a dynamo have to run in order to supply electricity for other purposes, and it can only be run under such conditions at a low load-factor, then it would pay to use its surplus power for charging cells.

The discharge from the cells can, in like manner, be economically used at any time when either a dynamo would otherwise have to run lightly loaded, as for example, when the load on the station was more than x dynamos could do, but considerably under the output of x + 1 dynamos. Or when the gain in efficiency by using the steam plant direct would be more than counterbalanced by the extra number of men required to work it. Or when, by taking a share of the load at the "peak," the total amount of the plant at the station may be reduced.

It may be therefore stated, as a general rule, that it will pay to use accumulators in a station if they can be both charged and discharged at a time when the steam plant or part of the steam plant would otherwise be working at an uneconomical load.

It is practically impossible, in any station, so to arrange matters that all the plant working shall be kept at an economical load for any length of time. The demand is constantly varying, and oftentimes in a most unexpected manner. So that in almost every station a set of accumulators would be of service, the cells being used to level the load on the plant. We all want our "load curve" to be a horizontal straight line, and accumulators will help us to obtain this by filling up the hollows with a charge and by leveling the peaks with a discharge.

Accumulators are of far more value in a station when used in this way than when kept for the purpose of acting as a stand-by in the event of a failure of any of the plant. Of course, when charged they are always available for this, up to the limit of their output, but primarily their use should be to supplement the plant by helping it to work at an economical load.

The prime cost of a battery for a given KW. output (for 5 hours) is roughly the same as for steam dynamos and boilers for the same output. The depreciation need not be more than 5 per cent. per annum, if properly treated and looked after, and this is about the same as for the steam plant.

We will briefly consider the use of accumulators in (1) the continuous current lighting station, (2) the alternating current lighting station, (3) the traction station, and (4) the combined lighting and traction station.

CONTINUOUS CURRENT LIGHTING STATIONS.

Continuous current lighting stations are now almost universally on the multiple-wire system, with either 3 or 5 distributors, and the battery is therefore divided into equal sections, the whole being however in one series. Fig. 1 shows an arrangement which is in use at a number of stations in this country.

It will be noticed that only two of the dynamos are connected with the middle wire. The others (generally of a larger size) are connected directly across the outers. Even though the accumulators may be large enough to take the difference in load between the two sides of the system, when the larger dynamos are running, it is not possible, or at any rate advisable, to connect all the machines directly to the outers, because the two sides of the battery may be discharged unequally, and it is therefore necessary to be able to charge them at different rates.

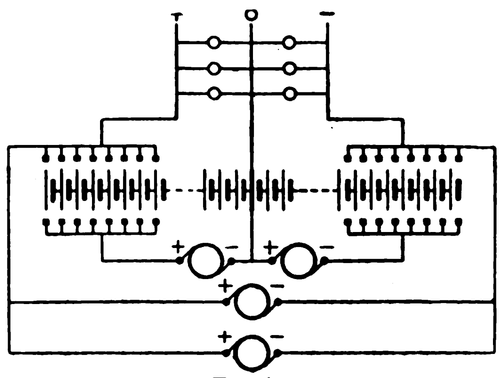

FIG. 1.

The larger machines need only give a voltage equal to that required on the feeders at the highest load. The two smaller ones must be able to give together a voltage at least 25 per cent. higher than this, in order to properly charge the cells. As is well known, the voltage of a cell remains sensibly constant during discharge, but during charge the back EMF. gradually rises, owing to the chemical action and the formation of gases.

One result of this rise of pressure at the terminals of the cells is that the battery must either be entirely cut off from the lighting circuit during charging, or else regulating switches must be used, so that the number of cells connected to the mains may be varied, and the pressure on the lighting circuit kept constant. And as the number of cells connected to the lighting circuit must be altered, so also must regulating switches be provided to vary the number of cells connected to the charging dynamos, in order that the end cells may be equally charged with the rest. These regulating switches are indicated in Fig. 1. It is extremely important to watch that the charging switches are never connected to a less number of cells than the discharging switches, or else the intermediate cells will be liable to be charged in the reverse direction.

It will be found practically impossible to prevent unequal charging and discharging of the end cells, particularly if there be any load on the mains while the charging is going on. Nothing is more liable to upset a battery as a whole than to have any cells unequally charged with the rest. Even at a little sacrifice of efficiency the battery should, as far as possible, be charged and discharged as a whole, in order that every cell may be equally treated. This is hardly possible by the arrangement shown in Fig. 1. Unequal use of the cells leads to unequal capacities, with the liability to reversal and all its consequent troubles.

For these reasons the arrangement shown in Fig. 2 is much to be preferred.

All the dynamos are connected directly across the outers, the two smaller ones having a middle wire connection as well. There are no regulating switches required at all, except when the battery is being discharged. The dynamos at all times give the voltage required on the bus-bars, and there is no need whatever to vary their pressure on account of the charging of the cells. The extra voltage required for the charging is added to the voltage of the bus-bars by means of a small "booster" in the cell charging circuit, and the rate of charge can be varied to any extent simply by varying its excitation. The boosters can be carried on extensions of the shafts of the smaller units, or may be motor driven if desired.

Each side of the battery may thus be charged and discharged as a whole, and when discharging its pressure is varied by means of back EMF. cells as indicated.

A sign of the times is the tendency to favorably consider the use of accumulators in sub-stations. They should be charged directly from the mains during periods of light loads, the extra voltage being obtained by means of motor-driven boosters. Not only the station plant but also some of the mains may by this means be kept economically loaded.

ALTERNATING CURRENT LIGHTING STATIONS.

Contrary to the general practice of engineers who have to use alternating current plant, the writer has for many years advocated the use of accumulators in such stations. Their uses are two-fold. They can be used as a standby for the exciting plant, and also, particularly in small stations, to keep up the supply during the hours of light load, through the medium of a motor-alternator. The day load plant could conveniently consist of an engine, alternator and dynamo on the same shaft, with a clutch coupling between the engine and the machines.

The alternator and dynamo should each be of the same output, and the engines sufficient to drive either at full load, or both at half load. During the daytime the engines would drive both, the alternator for whatever lighting there may be on the mains, and the dynamo for charging the cells. As the lighting load increased, so the charging current would be decreased, keeping the load on the engine constant. When it was desired to use the discharge from the cells, the engine would be uncoupled, and the dynamo, run as a motor, driving the alternator. This may be done either at the time of the "peak" of the load, thus reducing the demand upon the boilers, or at any time when there was only a small load on the station, such as after midnight or on Sunday mornings, so that a number of the staff may be relieved.

If the alternators be excited from bus-bars, fed by a common exciter or exciters, the cells would be joined in parallel with them, and the charging dynamo would take the place of all or some of the exciters.

If each alternator have a separate exciter, then change-over switches should be provided, so that the cells may be used on any machine when required, instead of its own exciter.

TRACTION STATIONS.

Accumulators have earned for themselves a bad name in connection with traction systems, because they have in most cases been carried upon the cars, each set having only its own car to propel. The result of this has been not only large cost in handling, owing to the removal of the discharged cells *en bloc*, and the substitution of a freshly charged set every few hours, but also rapid deterioration conse-

* Paper read before the Municipal Electrical Association, London, June, 1898.

quent upon the shaking and the heavy electrical strains due to frequently starting the cars.

With only one car to run, each set of cells has to be large enough for the maximum current taken at any time by that car, the average working current being not more than one-third the maximum. But when a number of cars are run from one battery, fixed either in the generating station or in a sub-station, a far less jerky curve is obtained. Owing to the improbability of all the cars starting together, the maximum output is much lower in proportion to the average output, and the strains on the cells are much reduced.

Large transformers in sub-stations are much more efficient, and with a given capacity in kilowatts will allow of much larger lamp connections than a number of small house transformers. In a similar way large batteries in stations or sub-stations are much more efficient, and with a given output will maintain a much larger car service than if divided amongst a number of cars.

Owing to the rapidly fluctuating load, the plant in a traction station is generally working only at a low average load factor. The machinery running must be capable of meeting the maximum demand, while the average load does not probably exceed one-half of the maximum. The advantages of accumulators are most apparent here, and the wonder is that more traction stations do not use them.

In the first place the accumulators would take the peaks of the load, thus relieving the machinery of the sudden jerks due to starting the cars, and in the second place the amount of running plant could be reduced to that sufficient for the average load.

The curves that were taken from an actual tramway system having eight cars running showed that the pressure varied from about 495 to 510 volts, the current taken by the cars from 300 to 375 amperes, and the dynamo output from about 115 to 150 amperes.

Without the accumulators, sufficient machinery would have to be kept running to supply the maximum load of 375 amperes, although the average load was not greater than about 150 amperes. As it is, one dynamo will easily do the work instead of two, and can be kept at a very regular load throughout the whole time, so regular in fact that lighting could easily be done from the same machine.

The cells in this case were connected as a whole directly to the bus-bars, in parallel with the dynamo, no regulating switches being used.

In order that the accumulators shall take their share of the load in this manner, it is necessary that they should be of ample size for the work, with a low internal resistance, and the dynamo should be shunt wound with a falling characteristic. When it is required to fully charge the cells a booster is generally used.

In order to assist the battery to discharge when the total load exceeds the output of the dynamos, and to charge when the load is less, a compound wound booster is sometimes used, in the manner indicated in Fig. 3.

The booster, which in the figure is shown motor driven, has two field windings in opposition to one another. When the line current is equal to the output of the dynamos, the two windings must neutralize each other, and the booster will give no pressure. Then the battery will neither charge nor discharge. When the line current is less than the output of the dynamos, the shunt winding will predominate, and the booster pressure will be in the right direction for charging the cells. When the line current is greater than the output of the dynamos, the series winding will change the polarity of the booster, so that it will add a pressure to the battery circuit, and thus help it to discharge. By means of the switch S, the battery can be connected directly to the line when required.

Prof. Mengarini of Rome uses automatic switches to vary the number of cells in the accumulator circuit, so that with a fixed machine voltage the battery may be charged and discharged at such rates as to maintain a constant output for the machines. At Leeds, also, automatic switches are used for the same purpose, worked by means of a relay and small motor. The great complication, however, introduced by the use of automatic switches, and the evils attendant upon the irregular charging of the end cells, are strong arguments against their use.

From the curves taken it was shown that if the battery be large enough for its work, and the dynamos shunt wound with a sufficiently drooping characteristic, it will not be necessary to use either a compound wound booster or regulating switches, in order to keep a steady load on the dynamos. It would be very interesting to know whether the automatic switches gave any trouble at Leeds, and whether they are still used.

Besides being used in the generating station, accumulators can be of great service in sub-stations, at the far end of long traction systems, for the purpose of keeping up the line pressure. They can be either charged by means of a special feeder from the generating station, or directly from the line during periods of light load, with the help of a booster.

A system of some interest is the combination of cells carried upon the cars, with the use of the overhead conductor, as at Hanover. In those parts of the town where the trolley wire is not permitted, the cars are run from the cells carried by them, while outside the town the ordinary trolley system is in use. The cells can be charged in position from the trolley wire, or at the station in the ordinary way.

Accumulators used in the generating station, or in sub-stations, should be mainly charged during the time the cars are not running, say from midnight to 6 A. M. During the remainder of the day they would be in parallel with the generating plant, to be used as required.

COMBINED LIGHTING AND TRACTION STATIONS.

The addition of a lighting load to the ordinary traction station may not be of much benefit to the latter, but the combination of a tramway and lighting load will be of great service to the lighting station. Attention was drawn to the many advantages to be gained by the lighting station from this combination, in a paper presented to this Association at its 1896 Convention, of which the writer was joint author, and a number of the practical points were considered in a contribution by the writer to *Lightning*, in November of the same year. It will not be necessary therefore to deal more than briefly with the subject at the present time.

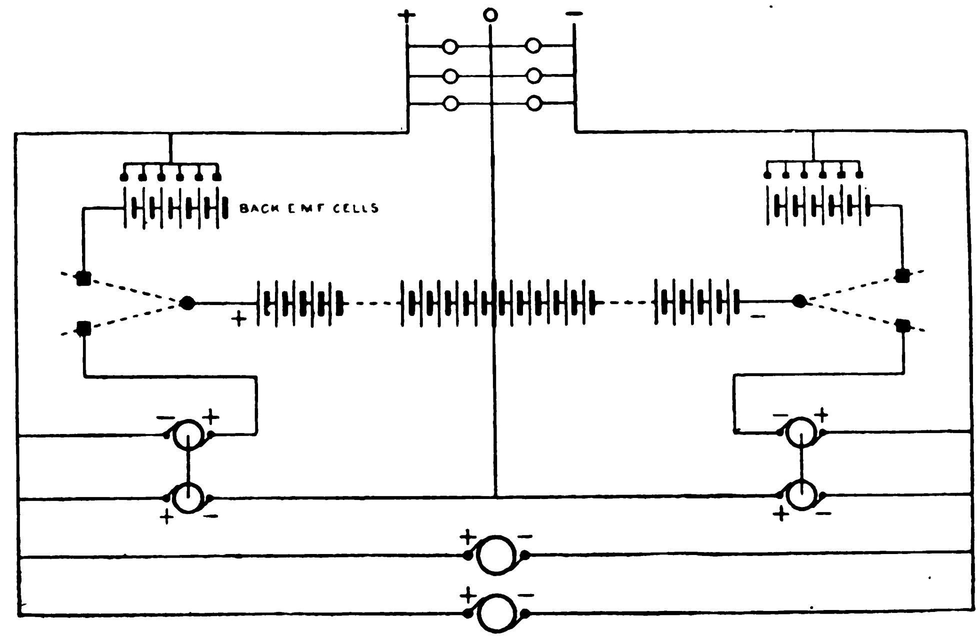

FIG. 2.

In arranging a combined lighting and traction station, the one aim of the engineer should be to use as much of the plant as possible for the combined purpose. The boilers and steam piping would be common in any case, and the engines (at any rate during the daytime) could be used to drive the lighting and traction machines at the same time. The exact method of arranging the plant would depend upon the local conditions, but by adopting one machine for traction and the other for lighting, the combined load could be taken by the same engines. A battery of accumulators properly arranged would prevent the fluctuations of the tramway load from affecting the lighting. During the evening, both machines could be used for lighting if desired, leav-

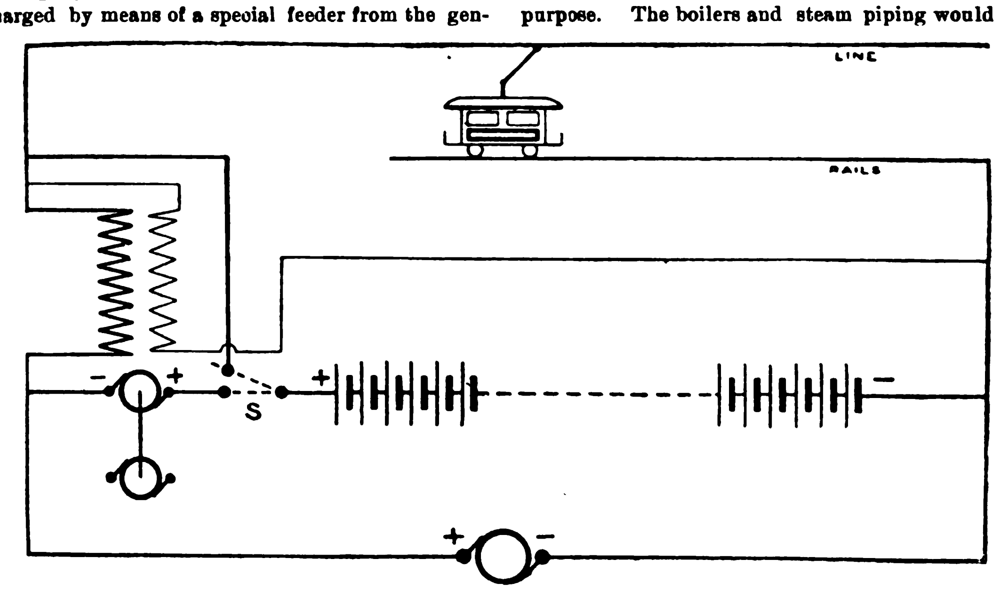

FIG. 3.

ing the accumulators to deal with the traction. After midnight the battery would be charged.

With a proper relation between the tramway load and the lighting load, it should be possible to have a nearly constant output for the boilers and engines throughout the 24 hours. The accumulators would look after the fluctuations in the daytime, and take the overlapping of the loads during the evening.

Before closing, the writer would like to draw attention to, and protest against, what seems to be a common practice amongst accumulator manufacturers. When maintenance rates are asked for and received, it will generally be found that, unless the capacity has been specified by the customer, the contractor will have offered to maintain the battery to not greater than from 60 per cent. to 70 per cent. of its original capacity. When a battery is put in to do certain work, it ought to be understood that its full capacity would always be required. But from the fact that most contractors will not offer to maintain 100 per cent. capacity without excessive terms, it would appear that batteries, as a rule, are rated too high in their lists.

ALUMINUM MANUFACTURE, WITH DESCRIPTION OF THE ROLLING-MILLS AND FOUNDRY AT MILTON, STAFFORDSHIRE.*

BY E. RISTORI.

(Concluded from page 72.)

Heavy Alloys of Aluminum.—There are many heavy alloys of aluminum, in addition to the well-known bronzes; some of these have not yet reached the development to which their valuable qualities entitle them, and which they will ultimately attain when better appreciated by mechanical engineers. Aluminum bronzes are undoubtedly superior in strength to most of the copper-tin bronzes now in use, and they are especially suitable for marine engineering. Propellers of aluminum bronze have been successfully made for most of the 26 and 30 knot torpedo-catchers, also a large number for the French Government. The two classes of bronze most frequently employed are marked R3 and R4. The difference between them is simply in the proportion of aluminum they contain. The following tests show their maximum, minimum and mean breaking loads and elongations, agreeably with which R3 has a guaranteed tensile strength of 35 tons per square inch with 25 per cent. elongation in 2 in., and when cast R4 breaks at 40 tons per square inch, with 10 to 12 per cent. elongation also in 2 in. These have the advantage of being considerably cheaper than other bronzes, are easily employed for any foundry work without special appliances or tools:

	Breaking load. Tons per square inch.			Elongation. Per cent. in 2 in.		
Mark.	Max.	Min.	Mean.	Max.	Min.	Mean.
R 3	43 7	39 6	41 8	13.00	6.50	9.75
R 4	36.6	30.8	34.0	35.00	15 50	23 30

Uses of Aluminum.—The principal uses of aluminum are too many to be enumerated. The properties of the metal are so akin to those of copper and brass that, broadly speaking, aluminum or one of its light alloys should to a large extent replace both copper and tin and also nickel or german-silver. Such a change would be followed by various advantages to all concerned. Not only would there be a considerable reduction in the weight of the articles, but they would not tarnish nor turn black on exposure to air. The cost should be the same, if not actually lower, inasmuch as, bulk for bulk, aluminum is already cheaper than copper or tin, and its price will continue to fall as the demand increases. One field, however, remains, which copper is bound to maintain as its own—namely, the construction of insulated electrical conductors. Experiments have already been made on a large scale with bare conductors of aluminum for telephones, etc., and the British Aluminium Company are using it in this manner at their Foyers works with perfectly satisfactory results, its conductivity, weight for weight, being double that of copper. But when the mains have to be insulated, copper is absolutely unapproachable, on account of its greater conductivity volume for volume, which is 165 per cent. of that of aluminum. Besides the advantages set forth above, aluminum is not poisonous, and is pre-eminently adapted for the manufacture of cooking utensils. On the other hand, tinware is not particularly cheap in the long run, for it is constantly wearing out; cast iron is heavy and brittle; and copper requires to be frequently retinned in order to avoid all danger to health. Inasmuch as an aluminum saucepan costs no more in the first instance than a copper one, weighs much less, is perfectly innocuous, and does not periodically need a fresh inside, it is not surprising that the employment of aluminum in kitchens and canteens is spreading rapidly.

A steady demand for aluminum is springing up in various kinds of printing processes as well as in lithography. The metal appears to answer admirably for the construction of rollers used in calico printing; and when its surface is properly prepared it is also capable of replacing the ordinary lithographic stone. It can easily be imagined that, instead of having cumbrous and heavy stones, which can be printed only on special slow-running "litho" machines, it is far better and cheaper to use thin sheets of a metal which can be bent into a circular form and printed on rotary presses. Bicycles of all kinds, electric light fittings, chains, bridles, stirrups, surgical instruments, sextants and other scientific apparatus, keys, cigar cases, pen and pencil holders, toilet articles, plates and dishes, spoons, forks, frames, name-plates, door furniture, hat and coat pegs, boot-trees, fire-engine fittings, business and visiting cards, photographic cameras, etc., are a few of the things that are being daily made in aluminum by various firms, and all these articles should be sold at the same price as if they were composed of brass. There are other instances where aluminum should economically replace commoner metals than copper or brass. Wherever a great deal of dead-weight has to be continually moved about, the cost of motive power, for which there is apparently no return, is serious, and if this unremunerative weight can be reduced to one-third of its present amount, in the course of a year or two the saving in power will more than compensate for the greater initial outlay. Thus frames for cabs and motor cars have already been made in aluminum; and though in England experiments have not yet been tried in this direction, aluminum railway carriage frames are under review in France. Especially for motor cars there should be a large field here for aluminum. A further demand for the metal will be brought about by its introduction into the military services. All parts of the soldier's equipment have practically been made already in aluminum, such as mess-tins, water-bottles, buttons, helmets, parts of rifles, cartridge-cases, fittings for guns, tents, horseshoes, portable bridges, etc. Nothing much has yet been done in England in this direction, but it is well known that Continental armies, notably that of Germany, are employing aluminum on a large scale. One of the largest uses to which aluminum has been applied is in metallurgy, where its valuable metallurgical properties were discovered and utilized. It is common knowledge among steel-makers that ingots often turn out spongy at the top; and when particularly good ingots are required, the faulty portion is cut off and melted over again. By the introduction of a very small proportion of aluminum to iron, steel or brass, either in the mold or in the ladle, the founder can be quite certain that the ingots will be solid all through. When used in this way, aluminum has the peculiar virtue of instantly liberating all the gases contained in the metal, and of keeping it fluid for a longer period, so that by the time the casting solidifies, the gases have had an opportunity to escape. In almost all steel works, and in all the principal foundries, aluminum is now being employed; and reports from some of these state that the result is a reduction in the wasters by 80 to 90 per cent. In this case aluminum does not actually replace any other metal, but by its own special qualities is useful as a means of improving physically and chemically some of its older rivals and friends.

Aluminum in Shipbuilding.—The use of aluminum in shipbuilding is growing rapidly, on account of the almost inestimable advantage of its great saving in weight. Four or five years ago a small canoe was made on the Thames of two sheets of aluminum stamped and riveted together. In 1892 Messrs. Escher Wyss, of Zurich, constructed a small launch entirely of aluminum, driven by a naphtha motor; and in the following year they built for Mr. Nobel another larger vessel, which has been in use ever since, and is now on one of the Swedish lakes. During 1894 and 1895 the author had on the Thames between Windsor and Maidenhead a similar vessel, which is now at work at Foyers. A much more ambitious attempt was made by Messrs. Yarrow in 1894. By request of the French Government they built of aluminum the whole of a second-class torpedo-boat, 60 ft. long by 9 ft. 3 in. beam. This boat weighed in full working order, but exclusive of armament, only 9½ tons, and attained during a run of two hours, carrying a load of three tons and with the engines indicating about 300 HP., a mean speed of 20¼ knots—an advance of 3½ knots over all previous records. Several yachts, including the "Vendenese," were also constructed at the same time, but they do not seem to have been a real and permanent success, owing probably to the adoption of an unsuitable metal. As pure aluminum was not strong enough alone, it was thought better to use an alloy containing about 6 per cent. copper in the construction of some of these boats. This alloy possesses a tensile strength of 14 tons per square inch; but, as already stated, this material is absolutely untrustworthy in sea-water, owing to the rapid corrosive action set up between its two ingredients. Moreover, although nobody would dream of employing any other metal than copper for plating sea-going vessels unless it were afterwards painted, aluminum has always been used bare, which the author considers a mistake. If the aluminum were protected from direct contact with the water, it would have lasted much better. Unfortunately this comparative failure has materially discouraged the adoption of aluminum in shipbuilding; and although it is now well recognized that the pure metal, and several of its alloys which do not contain copper, stand the action of salt water better than iron or steel, some time is likely to elapse before these premature tests are forgotten. Eventually, however, when further experiments have been carried out, there is no reason why a suitable alloy should not be adopted which, when properly used and protected from direct contact with sea-water, would resist corrosion as effectually as the majority of materials now employed in shipbuilding. These remarks refer only to the keel and other parts of the vessel below water, and chiefly to such craft as are to navigate the open seas. For all internal work aluminum is perfectly safe, and it is especially suitable for adoption in the navy, where the presence of wood and other inflammable material should be discouraged as much as possible lest it lead to fires during action. In all boats sailing on fresh or inland waters the corrosion is less, and when portability is desired, as in the case of expeditions to little known parts of the world, even if the aluminum do suffer corrosion, this is of trifling moment in comparison with the advantage of smaller weight to be transported. For instance, Messrs. David White of Glasgow have recently constructed an 18 ft. boat for a party going to Klondyke, weighing only 1¾ cwt.; it is wholly composed of aluminum, even to the rivets,

* Paper read before the Institution of Mechanical Engineers, Derby, Eng.

nails, bolts and nuts. It is made in sections which pack into one another, and the whole can be put into a box. Messrs. Forrestt & Son of Wivenhoe have also furnished a flotilla of two launches and a barge for Major Gibbons's trans-African expedition which started in May. The vessels are built in sections on the Hodgetts principle, each piece measuring about 6 ft. 6 in. by 3 ft. 9 in. and weighing less than 120 lbs., so that two natives can easily carry one between them by means of oars on their shoulders. The chief peculiarity of these boats lies in the interchangeability of the 20 sections composing the fleet. The different pieces can be put together in a variety of ways, forming three separate boats of such sizes as may be most convenient at the moment; it is possible to have either two 26 ft. launches and one 22½ ft. barge; or one 44½ ft. launch and two 15 ft. barges; or one 37 ft. launch, one 22½ ft. barge, and one 15 ft. barge, etc. One launch is fitted with an awning, the other carries a mast and sail.

THE MEASUREMENT OF THE EFFICIENCY OF DYNAMOS.*

In an article which was published in the *Revue de Physique et de Chimie*, M. Bunet describes various methods of testing the efficiency of electrical machinery, and discusses the relative advantages or disadvantages of the several methods. He divides them into two classes, in one of which the energy absorbed by the machine, P_a, and the useful energy delivered by it, P_u, are measured, whence the efficiency $\eta = \frac{P_u}{P_a}$, whilst in the other P_a or P_u is measured, and also the losses, p, whence the efficiency $\eta = \frac{P_a - p}{P_a}$, or $\frac{P_u}{P_u + p}$. In the first case measurements of electrical energy and of mechanical energy must generally be made, and the measurement of the latter presents considerable difficulty and cannot be made with the same accuracy as electrical measurements. The exception is where a motor and dynamo are coupled together and the electrical energy delivered by the dynamo is compared with the electrical energy absorbed by the motor, but in this case a difficulty arises in properly apportioning the losses between the two machines owing to the different conditions under which they are working.

Dealing with the first class of tests, the author mentions the method of measuring the mechanical energy absorbed by the dynamo by means of a transmission dynamometer, but finds it unsatisfactory on account of the want of accuracy of this instrument; the method of indicating the engine running light and driving the dynamo, and the method of determining the efficiency of the engine with a brake when it is running under the same conditions as when driving the dynamo; but both these latter methods are condemned as inaccurate. If the electrical machine to be tested is a motor, the brake method can be used and will give, with due precautions, results in which the error will not exceed 1 per cent. With regard to the method in which the dynamo is driven by an electric motor, the author proposes the use of a motor the efficiency of which has previously been determined, and this is a very convenient method of checking the efficiency of dynamos during their final run before delivery; but if a really accurate test of the efficiency is required, it appears to us that a method should be used which does not depend for its accuracy on the reproduction of exactly the same conditions in the motor at different times, and that it would be preferable even to test the dynamo machine as a motor by the method that has been considered good enough for the determination of the efficiency of the driving motor.

M. Bunet discusses this question of the relative efficiencies of the same machine as dynamo and as motor, and concludes that if the machine is in each case run so that the induced electromotive force is the same, and with the same currents through the armature and magnets, then the speed will be the same and the magnetic flux also. In such a case the C^2R losses are the same, as also are those due to friction, hysteresis and eddy currents, and if E is the induced electromotive force, C the current in the armature, R its resistance, W the losses due to friction, hysteresis and eddy currents, and W' the loss due to the exciting current, which is supposed to be supplied from a separate external source, then the efficiency of the dynamo will be

$$\eta_d = \frac{EC - C^2R}{EC + W + W'},$$

and that of the motor will be

$$\eta_m = \frac{EC - W}{EC + C^2R + W'}.$$

These two ratios will be very nearly equal, it is said, because the values of C^2R and W differ but little in most machines. M. Bunet assumes that the lead of the brushes is the same in both cases, and that the armature reaction requires the same compensating ampere-turns in the excitation, and says that this is borne out by his experience; but although the difference may be small, we should prefer to make the test by adjusting the exciting current till the speed was the same when the motor was supplied with current at a terminal potential difference equal to the terminal PD. of the dynamo plus twice the calculated drop in volts in the armature.

In the second class of tests M. Bunet first mentions the method proposed originally by Mr. Swinburne, in which the machine is run light as a motor at its normal speed with the magnets excited so that it runs at this speed when supplied with current at a pressure equal to the total EMF. it would generate at full load as a dynamo. Under these conditions, the speed and magnetic flux being the same as when running at full load as a dynamo, the watts supplied to the armature can be taken to represent the sum of the losses due to friction, hysteresis and eddy currents. The C^2R losses are then calculated from the measured conductor resistances of the armature and magnet windings, and the total losses obtained by adding to the C^2R losses the watts supplied to the armature when running light. It is often held that this method gives too high an efficiency, but M. Bunet gives comparative figures of tests by the Swinburne and other methods which show that this is not so to any appreciable extent. For example, a series motor supplied with 35 amperes at 230 volts had an efficiency measured by the brake of 86.3 per cent., and by the Swinburne method of 87 per cent.; a second motor receiving 25 amperes at 230 volts had an efficiency by the brake of 84.4 per cent., and by the Swinburne method of 83.7 per cent.; whilst a third motor receiving 40 amperes at 230 volts had an efficiency by the brake of 88.3 per cent., and by the Swinburne method of 87.5 per cent. Again, two dynamos of 600 volts and 410 amperes at 425 revolutions were tested by the Hopkinson method, being coupled together by a belt, and had an efficiency of 91.3 per cent. at full load, while by the Swinburne method the efficiency worked out at 92.5 per cent. A series of tests taken at various currents from 150 to 415 amperes gave efficiencies by the Swinburne method which were from 0.4 per cent. to 1.2 per cent. higher than those obtained by the Hopkinson method, but this is only what would be expected as in the latter cases the loss in the belt drive is included.

The method employed originally by Dr. Hopkinson consisted in coupling together mechanically and electrically two similar machines, one of which ran as a generator and supplied current to the other, which, running as a motor, supplied the greater part of the mechanical energy required to drive the generator. The energy required to make up for the losses in the two machines and to keep the combination running was supplied from an engine or other motor and was measured by a transmission dynamometer. Besides possessing the advantage that when testing large machines it is only necessary to supply from an external source less than a fifth of the energy that would be required to drive one of the machines as a dynamo, there is the further advantage that an error in the dynamometer reading causes a much smaller percentage error in the efficiency. M. Bunet says that an error of 5 per cent. in the dynamometer only causes ¼ per cent. error in the efficiency if this is about 90 per cent.; but this is a slip and should be ½ per cent., unless when he speaks of an efficiency of 90 per cent. he means that the efficiency of the combination of two machines is 90 per cent. The transmission dynamometer is not now much used, and the method of making this test has been modified so that all measurements are electrical, the energy required to make up the losses being supplied by a dynamo which is coupled up either so that it works in parallel or in series with the generator under test. In the former case the auxiliary dynamo must supply current at the same voltage as the machines under test, while in the latter case it must be capable of carrying the main current in its armature, and of the two methods M. Bunet recommends the former, because it is easier to regulate the speed of the machines.

There has been a good deal of discussion at various times as to the proper way of deducing the efficiency of each machine from the combined efficiency of the two, which of course is what is actually measured by the test. M. Bunet says that if the square root of the combined efficiency is taken as the efficiency of each machine, an error of as much as 2 per cent. may be made, according to the conditions under which the machines are run. He recommends as the best conditions for making the test, that if E is the normal voltage, C the normal current, and R the resistance of the armatures, the dynamo should be run so that at its normal speed it gives a potential difference at the terminals of $E + CR$. The magnetic flux in the dynamo will then have to be increased from the normal in the proportion of $\frac{E + 2CR}{E + CR}$, and that in the motor diminished from the normal in the proportion of $\frac{E}{E + CR}$; but as this increase and decrease are small, say 2 or 3 per cent., and as the mean of the two fluxes is practically equal to the normal flux, no appreciable error is made in assuming that the losses in one machine in hysteresis and eddy currents under normal conditions are equal to half the losses from the same cause in the combination. The same applies to the friction losses as the machines are running at the same speed, and to the exciting current losses as the normal exciting current is practically the mean of those in the generator and motor under test conditions. The current in the motor armature will, however, be greater than that in the generator armature by an amount equal to C_1 if that is the current supplied by the auxiliary dynamo, and to correct for this M. Bunet gives the following formula for the efficiency of one machine as a dynamo:

$$\eta = \frac{EC}{EC + \frac{EC_1}{2} - \frac{R}{2}\left\{(C + C_1)^2 - C^2\right\}}$$

As the C^2R losses in the armatures and magnets can so easily be separated out, the writer prefers to calculate them and deduct their sum from EC_1, and then allot half the remainder to each machine as the sum of the friction and core losses, and to calculate

*From the *Electrical Review*, London.

the efficiency of the machine as would be done if the Swinburne method had been employed.

If the auxiliary dynamo is connected in series with the machines under test the best conditions are those which make the mean of the potential differences at the terminals of the dynamo and motor armatures equal to the normal voltage, i. e.,

$$E_d + \frac{e}{2} = E_m - \frac{e}{2} = \text{the normal voltage, where}$$

E_d, E_m and e are respectively the terminal potential differences of the dynamo, motor and auxiliary dynamo. For this test the writer prefers, if possible, to separately excite the magnets of the machines under test, reducing the excitation of the dynamo and increasing that of the motor so that the machines run at normal speed. In this case the current through both armatures is the same, the frictional losses are equal, and as the magnetic flux in the motor is as much above the normal as that in the dynamo is below, there is no appreciable error in assuming that the hysteresis and eddy current losses under normal conditions are equal to half the loss from these causes in the combination. The efficiency of either machine as a dynamo at its normal output of E volts and C amperes is

$$\frac{E\,C}{E\,C + \frac{e\,C}{2} + W'}$$

where e is the potential difference of the auxiliary machine and W' the watts lost in excitation at normal load.

There is, we think, no doubt that the Swinburne and Hopkinson methods of testing are far ahead of any others in accuracy, and that the choice of one or the other method may be determined simply by which is the more convenient in any particular case. If there are not two similar machines available, the Swinburne method should be employed, and the conductor resistances should first be measured cold; the dynamo should then be run at full load for several hours and the conductor resistances again measured hot, and after this the machine should be run light as a motor to determine the friction and core losses. If two similar machines are available, the Hopkinson method is preferable, as the full load test only requires an engine or other motor capable of supplying a fraction of the power absorbed by the generator, and it is not necessary to have resistances to carry the output of the dynamo. The writer has found no difficulty in making the test under good conditions with the auxiliary dynamo in series with the machines under test, and finds so little difference in the two methods that one or the other may be used according as the output required from the auxiliary dynamo will best suit an available machine.

THE ASHCROFT ZINC EXTRACTION PROCESS AT COCKLE CREEK.*

The Ashcroft zinc extraction process for the extraction of zinc from mixed sulphide ores by means of electrolytic deposition became the property of the Sulphide Corporation in the year 1895, and after trial at the experimental works at Grays, in Essex, steps were taken to test its value upon a large industrial scale at the Broken Hill Mines in New South Wales. In a recent article contributed to the *Elektrochemische Zeitschrift* by Dr. Richard Threlfall, a very full description of the process and of the plant erected at Cockle Creek is given, with illustrations of the generating plant, the leaching vats and the electrolytic tanks. Since the date of this article it has been publicly announced that the economic results of the first trial at Cockle Creek have not been successful, and that the electrolytic plant is to be shut down, while the operations of the Sulphide Corporation are to be confined to the concentration and smelting of the raw ores. On account, however, of the importance of this attempt to work the refractory Broken Hill ore by an electrolytic method, and on account of the probability that further efforts will be made to render the electrolytic process a success, we give our readers below a fairly full abstract of Dr. Threlfall's article.

The Broken Hill ore contains on the average 30 per cent. lead and 30 per cent. zinc as sulphides, with 25 oz. silver to the ton. Some portion of the lead is separated from the zinc in the concentrating plant, and the latter portion of the ore with its silver contents is then subjected to the Ashcroft treatment. This consists in first crushing the ore, and then roasting it under such conditions of temperature and access of air that the zinc sulphide is transformed into a mixture of oxide, sulphate and basic sulphate. The roasted ore is then charged into leaching vats constructed of wooden staves, and of circular form, where it is leached with a solution containing 10 grammes iron as chloride, and an equivalent amount of sodium sulphate per liter. The zinc passes into solution according to the following equation:

$$3ZnO + Fe_2Cl_6 + 3H_2O = 3ZnCl_2 + Fe_2(OH)_6,$$

while the iron, lead, manganese and silver remain in the leaching vat. The leaching is repeated with the same volume of solution until its zinc contents reach 30 grammes per liter. It is then freed from the small quantity of iron and silver which it contains by heating with zinc oxide, and by passing through filter presses in order to remove the precipitated impurities.

The solution of zinc chloride is now ready for the electrolytic procedure. This is carried out in wooden tanks 6 ft. by 6 ft. by 6 ft. constructed of California red wood, each tank being divided into four compartments by means of wooden partitions and canvas. Each tank contains 52 anodes and 48 cathodes, the dimensions of these being in every case 4 ft. by 1 ft. This comparatively small size enables them to be easily handled by the workmen. The anodes in two-thirds of the tanks are of iron, in the remaining third they are of carbon. The cathodes are in every case of thin rolled zinc, $\frac{1}{25}$ in. thick. It is not possible to clearly explain the electrode arrangement without the explanatory diagrams, but briefly it is as follows: The zinc chloride solution first traverses all the cathode compartments of the system of vats; in these zinc is deposited by the action of the current. The effluent from the cathode compartments contains 12 grammes zinc per liter (it is not economical to go below this limit), and it is now passed through the series of anode compartments of the same system of vats. In those containing iron anodes, iron is dissolved in equivalent amount to that of the zinc deposited, while in the remaining third this ferrous chloride is raised to the ferric state by the chlorine liberated at the carbon anodes.

The chemical equations for these reactions are as follow:

$$ZnCl_2 + Fe = FeCl_2 + Zn$$
$$2FeCl_2 + Cl_2 = Fe_2Cl_6.$$

The electrodes are connected in parallel, and the vats in series; the EMF. varies from 1 to 2.8 volts, according as iron or carbon anodes are used. The system of vats is so arranged that the whole number absorb 120 volts—the pressure at which the generating plant delivers the current in the vat house. A current-density of 5 amperes per square foot is obtained under these conditions, and the cathode area is sufficient to permit of 5,000 amperes being passed through the system under normal conditions of work. One of the great difficulties in zinc deposition is to avoid the formation of zinc sponge at the cathode. It is evident that there have been unpleasant experiences of this kind at Cockle Creek, and Dr. Threlfall states that Ashcroft has sought to overcome the difficulty by adding zinc oxide or caustic alkalis to the electrolyte before it passes into the cathode series of cells. He himself expresses doubts as to the value of this addition, and states his belief that unsatisfactory deposits of zinc are caused by small quantities of unrecognized impurities in the electrolyte. When once a solution of zinc has been obtained which yields a dense metallic deposit of zinc at the cathode, he states that current-densities varying from 2 up to 110 amperes per square foot may be used without detriment to the metallic characteristics of the deposit.

The generating plant at Cockle Creek consists of five Babcock & Wilcox boilers each of 500 HP. capacity. These supply steam to 5 Wilans engines direct coupled to 5 Siemens dynamos. The smaller machines deliver 1,100 amperes at 120 volts, the larger ones 2,200 amperes at 120 volts. Each dynamo is provided with a separate switchboard, through which it is connected to the common conductor. The electrolyte is maintained in rapid circulation through the electrolytic vats. This is effected by means of four large storage tanks placed at the end of each double row of depositing vats. These tanks are at different levels, and pumps are used to raise both the anode and cathode supply of electrolyte to the higher storage tanks, from which it flows by gravity through the system of vats back into the ower storage tanks.

The above plant was put into operation in March, 1897, and during a run of four months produced 150 tons of zinc. The economic results were, as already stated, unfavorable, and the directors of the Sulphide Corporation decided that if, after some alterations in the plant had been carried out, a second run of three months did not yield better profits, the electrolytic recovery plant must be stopped.

This second trial run at Cockle Creek was commenced in November last, and although no public announcement concerning the result has yet come under our observation, we hear from private sources that the production of zinc was again unsatisfactory and insufficient to give financial stability to the process. In view, however, of the money sunk in the machinery and plant at Cockle Creek, it is probable that further attempts will be made to render the process a success, especially as Mr. Ashcroft is understood still to have faith in the possibilities of the electrolytic method of treatment for refractory sulphide ores.

* From the *Electrician*, London.

LONDON NOTES.

[From our London Correspondent.]

The Caustic Soda Litigation.

Judgment has been given by Mr. Justice Bigham in the London Law Courts in the action brought by the Castner-Kellner Alkali Company against the Commercial Development Corporation, Ltd., for an infringement and to restrain further threatened infringement of letters patent No. 29,259, of 1894, for an improvement in electrolytic apparatus for decomposing metallic salts. His Lordship decided that plaintiffs were entitled to succeed, and he granted an injunction as asked for. The infringement consisted of the use of certain apparatus made according to the specification and other letters patent, No. 21,509 of 1896, belonging to the defendants.

Alternate Current Plants and the Zipernowski Patents.

Manufacturers of alternating current plant and those engineers responsible for alternating current lighting stations in this country are understood to be threatened with possible litigation by one Martin Rucker, who is stated to have purchased the Zipernowski & Deri transformer patents of 1885, and is now claiming royalties from users for infringement. The London electric lighting companies and some provincial municipalities have received letters to some such effect, and it is expected that they will combine to resist what are considered to be attempts to place a heavy tax upon electric lighting undertakings. The patents which are declared to be infringed are said to be respecting the working of transformers in parallel.

LEGAL NOTES.

The Second Appellate Division of the Supreme Court of New York has affirmed the verdict of a jury awarding $7,500 to Olga Paulsen for injuries received in jumping from a car of the Nassau Electric Railroad Company in Brooklyn on the 12th of August, 1896. The plaintiff while a passenger on the car with her 12-year old niece, becoming alarmed by the flashing from the controller or motor box situated at the front railing of the car, jumped from the car while it was in motion and fell to the ground, breaking her leg and receiving other severe injuries. In the action brought by her against the railroad company to recover damages, there was evidence tending to show that the flashing was of an unusual character; that the controller was out of order, and that the car had not been inspected before it left the depot on this trip. The Appellate Court, Justice Goodrich presiding, held that the question of the defendant's negligence was properly submitted to the jury and that the judgment should not be disturbed. It was held that negligence might also be imputed to the railroad company from the fact that the motorman, after the flashing or flaming began, permitted the car to continue its course without stopping to ascertain the cause of the flame, until a new element of apprehension was reproduced by the burning of the fuse.

At Trenton, N. J., on the 12th inst., Vice-Chancellor Emery denied the application of the township committee of Summit for an injunction restraining the New York & New Jersey Telephone Company from running its wires through certain streets in the township. The Vice-Chancellor says the poles upon which the wires are suspended are upon private property by consent of the owners, and where wires cross streets the consent of the owners of the land abutting has been obtained. The wires are suspended at an elevation which does not interfere with public travel. The township committee claimed that the telephone company had no right to suspend its wires across the public streets without the consent of the township committee. Not long ago the committee caused the wires to be cut and the company replaced them.

CANADIAN NOTES.

The Board of Governors of McGill University, Montreal, have appointed Prof. R. B. Owens, E. E., of the University of the State of Nebraska to the chair of electrical engineering at McGill.

The Jacques Cartier Water Power Company of Quebec has been organized with the authorized capital stock of half a million dollars. The company has acquired from the Standard Light & Power Company of Montreal its chartered rights to introduce electricity for light, power and heating throughout the city of Quebec. It is expected that the company will have the work in full operation on or before the first day of January next.

The Ottawa city council has passed the Metropolitan Electric Company's bye-law which lets in a new electric corporation to operate in Ottawa. The bye-law provides among other things that the company is not to charge for incandescent lighting more than one cent per ampere hour, with a discount of 40 per cent. and a further discount of 12 per cent. for cash within 15 days, off the lowest meter price. At the expiration of ten years the city has a right to acquire the property of the company at its actual cash value. The company has made arrangements for obtaining its water power at the Chaudiere Falls and has already secured over 2,000 horse power to begin with and an option for 5,000 more if needed.

Personal.

Mr. Martin J. Insull, brother of Mr. Samuel Insull, president of the Chicago Edison Company, who has until recently been connected with the well-known firm of Sargent & Lundy of Chicago, has opened an office in that city at 1013 Monadnock Block, as manufacturers' agent, and will continue to handle dynamos, motors, incandescent lamps and other electrical appliances. He has our best wishes, and with his well-known ability cannot but make a success of the undertaking.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING PLANTS.

Abilene, Kan.—An electric light plant is to be built here at once, the council having voted to light the streets with arc lights.

Bristol, R. I.—The consolidation of the Bristol Gas & Electric Lighting Company and the Narragansett Electric Lighting Company of Providence having been completed, the plants of Bristol and Warren will be closed and all the electricity needed for those places will be furnished from Providence. The new corporation, which retains the name of the Providence company, is capitalized at $200,000, and its officers are as follows: President, Samuel P. Colt; vice-president, John Waterman; treasurer, Wm. R. Bogert; board of directors: Samuel P. Colt, Leander R. Peck, John Waterman, Marsden J. Perry, B. M. Bosworth, Wm. T. C. Wardwell, J. H. Manchester, Joseph W. Martin and Wm. Russell Bogert.

Brooklyn, N. Y.—The Edison Electric Illuminating Company's bids for supplying the borough of Brooklyn with electric lights were as follows: For more than 3,500 lights, each of 1,200 candle power, 34 cents each per night; 600 candle power, 17 cents per night; for less than 3,500 lights, each 1,200 candle power, 35 cents each per night; 600 candle power, 18 cents each per night; for public buildings, 16½ cents per KW. hour for current furnished. These are the same as last year's contract prices, and as the company was the only bidder, will probably be accepted. The Edison Electric Illuminating Company is the one which has been practically absorbed by the Kings County Electric Light Company. The Kings County Electric Company's bid, made when the proposals were first advertised, was 31 cents per night; that of the Edison Company, 35 cents per night. The specifications called for the lighting of all Brooklyn by one company. Corporation Counsel Whalen handed down an opinion in which he said this specification should be eliminated and a readvertisement of the proposals made. This was done, but not until several weeks had passed. In the meantime the Edison Company had been absorbed by the Kings County Company.

Caro, Mich.—The local electric light plant has been purchased by Charles Montague and J. H. Harris. The purchase includes all the property surrounding the plant—elevator, tile yards, stock yard, etc. A stock company is being formed with a capital of $30,000, under the title of "The Caro Light, Power & Grain Company," and as soon as the articles of association are filed with the Secretary of State the stock books will be opened.

Chicago.—A deal is said to have been completed by which the Chicago Edison Electric Light Company has absorbed every important corporation now furnishing electric light within the city limits. The companies which have been absorbed are: Hyde Park Thomson-Houston Light Company, Hyde Park Electric Light & Power Company, People's Light & Power Company, People's Electric Light & Motor Power Company (town of Lake), Mutual Electric Light & Power Company (Hyde Park), Englewood Electric Light Company, West Chicago Light & Power Company, Western Light & Power Company (Lakeview), Edgewater Electric Light & Power Campany, Chicago Sectional Electric Light Underground Company, Commonwealth Electric Light Company.

Dickson, Tenn.—The Business League is considering a proposition to light this town with electricity.

Gallatin, Tenn.—The board of aldermen has decided that the town should put in an electric plant at its own expense and not give the franchise to any firm or corporation.

Herington, Kan.—The council has determined to close down the city electric light plant owing to the excess of expenses over receipts. The deficiency up to the end of last year was $5,200, and for some time it has been running behind at the rate of $150 to $200 a month.

McArthur, O.—Bids will be received by the trustees of the electric works of this village until the 25th inst. for furnishing machinery, material and performing the labor necessary for the construction of an electric lighting system for the village. Bids must be addressed to James W. Darby, clerk, at whose office plans and specifications can be seen.

Mystic, Conn.—The plans for starting an electric light plant in this village are maturing. A company is already organized with a special charter, and it only remains to elect directors and officers and to provide for an increase of the capital stock to $15,000. Thomas C. Perkins of Hartford is the promoter of the project.

New Orleans.—The fire and lighting committee of the council has shaped an ordinance embodying the requirements to be met in submitting proposals for lighting the public buildings, parks, etc., for a term beginning in March, 1899, and ending on the 31st of December, 1902, and the city attorney having approved the ordinance, it has been sent to the council. The document is published in full in the "Picayune" of the 6th inst.

Paris, Tex.—Bids will be received at the mayor's office until September 1 next for the lighting of this city with electric arc lights for a period of from one to five years. The bids must be for not less than 60 nor more than 100 arc lights, and must be accompanied by a certified check for $500.

Penn Yan, N. Y.—The Penn Yan Electric Light & Power Company has signed the lighting contract for another year. The price agreed upon is $3,876.

Providence, R. I.—The consolidation of the Bristol County Gas & Electric Company with the Narragansett Electric Lighting Company has been effected.

Torrington, Conn.—The Torrington Electric Light Company has voted to increase its capital from $24,000 to $50,000, for the purpose of putting in a gas plant in addition to its electric lighting system.

Vicksburg, Miss.—The recent explosion of a cylinder in the electric light plant here caused more damage than was at first supposed. The damage is now estimated at $1,000, and it will take two weeks to put the plant in order.

Wellington, Kan.—The prospecting for water on the Ninnescah, near Belle Plaine, is progressing satisfactorily. If sufficient water can be found, the city council will have the water piped to this city, and will also have an electric plant erected there and current transmitted to the city for lighting purposes.

STREET RAILWAYS.

Ballston Spa, N. Y.—The Ballston Terminal Railroad is completed to a point within one and a half miles of Rock City Falls. It is quite unlike any other trolley road in existence, designed mainly to carry freight from the various large paper and pulp mills and iron factories along the Kayaderosseras, yet it runs through some of the most picturesque scenery in the State and is quite likely to become a very popular road for passengers who like a pleasant ride through the country which it traverses.

Brooklyn, N. Y.—The Brooklyn Elevated Railroad Company will begin changing the motive power of its road next month. About two thirds of its mileage will be equipped with the electric system, and on this portion of the line steam locomotives will be altogether abandoned. The cost of the change will be in the neighborhood of $800,000.

Brockton, Mass.—A new signal system has been introduced on the Taunton & Brockton street railway. It is called the Skeen automatic semaphore signal system and is made by the Skeen Company of St. Louis. The Brockton, Mass., "Times" states that the Brockton company was the first to make application for the use of it on the road between Brockton and Taunton. It is a complete block system, front and rear, and its principal virtue lies in the fact that it is entirely automatic. No hand is needed to operate it, no eye to guide it. A man may sleep at his post, and still it works as though he were awake, and it is never out of order. It is similar in a certain respect to the signal system used extensively on the steam railroads, being worked by electrical contact. The Skeen system is operated from the trolley, and throws a red light ahead and a white or "telltale" light behind, to show that everything is all right. Besides the lights, it operates semaphores, which work independently, and these, even if the lights fail to work, notify the motormen of all changes.

Chicago.—Two storage batteries of 500 KW. capacity, or 700 horse power each, are being installed by the South Side Elevated Company. The installation is being supervised by Sargent & Lundy, and is expected to be completed by September 30. The batteries are to be used for the purpose of evening the load on the engines.

Elizabeth, N. J.—Judge Van Syckel has refused to issue an injunction restraining the Union County board of freeholders from granting a franchise to John Kean to construct a trolley road on the main county road from Elizabeth to Plainfield, for which Mr. Kean has offered to pay $250,000. The Union County League, which is opposed to the scheme, petitioned the court for the injunction which has been refused.

Erie, Pa.—E. T. Moore, of this city, who is interested in the new electric line between Erie and North East, says that parties in Cleveland are pushing a movement to build a line from Painesville to Conneaut, O., and that the line may be later on extended westward to Erie to connect with the North East and Erie motor line. Mr. Moore says it is only a matter of a few years when motor cars will be running direct between Cleveland and Buffalo.

Escanaba, Mich.—The Escanaba Electric Railway Company, which has been reorganized will put the road into good condition and connect it at Wells with the Soo line. Additional cars will be purchased and sheds built. Parks and resorts will be made along the Escanaba river and it is expected in the near future the road will be extended to Gladstone.

Milwaukee, Wis.—Contracts have been let for the construction of the new power house of the Milwaukee Electric Railway & Light Company at River and Oneida streets, which will cost $600,000. It will be an ornamental and imposing structure of steel, stone and terra cotta.

New York.—It is officially stated that as soon as the Sixth and Eighth avenue roads are electrically equipped, the Metropolitan Street Railway Company will change its Broadway and Columbus avenue cable lines to underground trolley.

New Britain, Conn.—A comparison has been made covering five months with steam and five months with electricity between New Britain and Hartford. The steam road took in $135 a day, 750 passengers, while the third rail line took in $258 from 2,587 passengers per day.

New Brunswick, N. J.—The New York & Philadelphia Traction Company is making progress with its plan to extend its road from Bound Brook to Trenton. The company has secured franchises for the extension from Bound Brook to New Brunswick, where it will connect with the system of the Brunswick Traction Company. This will form part of the line to Trenton, the road branching off some distance from this city and going to Middlebush. Surveyors are now at work staking off the line from Bound Brook to Kingston. From Kingston it is the intention to proceed to Princeton and thence to Trenton. This will complete the system in Central New Jersey and be an important link in any trolley system crossing the State.

North Granville, N. Y.—There was a meeting in this place a few days ago in the interests of the proposed Whitehall-Granville electric railway. The object was to take the final steps towards procuring incorporation papers. Among those present were C. L. Baker of Troy, H. H. Burleigh, Judge T. A. Lillie and R. M. Witherbee of Whitehall, D. D. Woodard, president of the Granville National bank, Supervisor Norton of Granville, G. N. Finch and William Munson of that village. An adjournment was taken until August 16, when a meeting will be held at the law office of Potter & Lillie in Whitehall.

Quincy, Ill.—The electric street railway system was sold on the 5th inst. to a Maine syndicate represented by W. B. McKinley, of Chicago, for $220,000. The same syndicate controls street car systems and light plants in Joliet, Bay City, Champagne, Springfield, O; Trenton, Mo., and other cities. The syndicate will at once spend $100,000 for extension and rolling stock.

Richmond, Va.—An electric road between this city and Tappahannock is strongly advocated in the columns of the "Dispatch," which produces facts from a Tappahannock journal going to show that such a road is imperatively needed by the farmers and others living along the route and would be of great advantage to Richmond as well as to Tappahannock.

San Francisco.—It is probable that the Sutter Street Railway Company will soon acquire the Sutro electric line by purchase. The Sutro line was built for the sole purpose of forcing a 5-cent rate from the ferries to the Cliff, where Adolph Sutro had erected extensive pleasure grounds. The old lines refused to make the rate and Sutro was determined to force it in order to make his resort more popular and his property more valuable. It was stocked for $400,000 at $10 a share.

Sandusky, O.—The Cleveland capitalists, comprising the Sandusky & Interurban Electric Railway Company, who recently purchased the Sandusky Electric Railway have been inspecting the lines of the People's Company and Sandusky, Milan & Norwalk Company, with a view to their purchase if possible and the consolidation of the three Sandusky lines under one management before building the extensions east to Lorain and west to Toledo.

Steubenville, O.—An electric railway route is being surveyed between Steubenville and Mingo Junction. It is expected if the line is built to extend it to Toronto, O., and then to connect it with the Wellsville & East Liverpool Street Railway.

Toledo, O.—The "News" states that work on the Chicago, Detroit & Toledo Electric Railway will commence in a short time. The road was formerly called the Ohio & Michigan Traction, and the company was originally formed by Charles W. O'Brien, Leopold Freud and A. E. Riopelle, who procured right of way from the townships of Ecorse, Monguagon and Brownstown, in Wayne county, and Frenchtown, Erie, Lasalle and Monroe townships and the city of Monroe in Monroe county, Mich., as well as Washington township in Lucas county, O., and also connecting arrangements with the Toledo street railway system. The present company was organized about three months ago, and has the following officers: President, J. C. Shaffer, Chicago; vice-president, Leopold Freud, Detroit; secretary, Frederick S. Mordaunt, Chicago.

Waterville, Me.—It is reported that about $16,000 has been secured in subscriptions toward building the Waterville & Wiscasset Railroad, and that there would be little trouble in getting subscriptions enough to bring the total up to $50,000. Frank Redington of this city is president of the company.

Waynesboro, Pa.—The project for an electric railway for Waynesboro, which has been under consideration by a local syndicate for some months past, is now beginning to assume definite proportions. The scheme which will be, it is said, pushed ahead, is for a line to connect Waynesboro and the South Mountain resort system. Some months ago a company composed mainly of Baltimoreans was chartered under the name of the Blue Ridge Railway Company. Since the organization of this company the matter has been at a standstill until within the past week, when capital to the amount of several hundred thousand dollars is said to have been pledged.

Wilmington, Del.—It is confidently predicted by those in a position to know that within six weeks trolley cars will be running between Wilmington and Chester and Philadelphia. Rights of way under condemnation proceedings are being rapidly acquired in Delaware, and there appears to be no apprehension about any further obstacles.

MANUFACTURING, ETC.

Fort Wayne, Ind.—The Fort Wayne Electric Corporation has just sold to the lighting company at Montreal, Can., equipment for a 500 arc light plant.

Hoboken, N. J.—Plans have been prepared for an electric elevator on the inclined system for carrying cars and loaded trucks up the bluff just south of the West Shore Ferry at Weehawken. The structure will be about 300 feet long and the cost of the work and its electrical equipment will amount to $200,000.

Middletown, Conn.—The report is current here that Charles E. Dustin of Hartford, the former president of the Schuyler Electric Company, has subleased from the Worcester Cycle Company the Schuyler plant in Middletown, and that he will conduct an electrical business there.

New York.—Lewis Degen, an engineer for the General Electric Company, who has just returned from an extensive trip through Brazil, is reported in the "Journal of Commerce" as saying that the German electrical companies are acquiring a strong foothold in the Brazilian electrical field, for the reason that most of the business is transacted on time. In Rio de Janeiro the Siemens & Halske Company of Berlin has made some good contracts. American companies could secure more business in some of the South American countries if they cared to extend payments for their goods, but as it is, in transactions with this country, when they are direct, payment is required against bills of lading.

COMPANY MATTERS.

Jackson, Mich.—A decree has been entered in the Circuit Court here ordering the sale of the street railway by the Circuit Court commissioner, naming the time after August 31, to satisfy the mortgage held by the Fidelity Loan & Trust Company. The amount claimed is $171,829.50. The property has been in the hands of a receiver for the past year.

Pasadena, Cal.—The Edison Electric Company of Los Angeles has purchased the entire stock of the Pasadena Electric Light Company. About October 1 this company will begin furnishing power for itself and the Los Angeles Railway Company in Los Angeles and the Pasadena Electric Light & Power Company and the Pasadena & Los Angeles Electric Railway Company. The officers of the company are George H. Barker, president; William R. Staats, secretary; John B. Miller, treasurer.

NOTES FROM A CORRESPONDENT.

Amsterdam, N. Y.—The town board of the town of Florida has granted a request of De Witt A. Devendorf of Fort Hunter to string wires to convey the power from the electric plant at Mill Point to Amsterdam. The power will be used to run the electric cars in Amsterdam and also for electric light purposes.

Mechanicville, N. Y.—The Hudson River Power Transmission Company has started its plant at the new dam, with 2,000 horse power, 12,000 volts, and it will run continuously hereafter. Connection with the Edison works has been completed, and power to run that plant will be furnished from the power station at Furman Falls. Power for the street car line at Schenectady will also be furnished from Mechanicville.

Schenectady, N. Y.—Mr. F. O. Blackwell of the General Electric Company works delivered an address Thursday evening, August 11, before the Technical Association of this city. The subject of the lecture was "The Value of Water Power for Electrical Distribution of Power." It was well presented and was appreciated by all who were present.—A distinguished party of representatives of the Imperial Russian army and navy visited Schenectady, August 11. They visited the General Electric Company's works and were shown through the various departments.

Watervliet, N. Y.—The electric light commission has given to the Fort Wayne Electric Corporation the contract to construct two dynamos and to furnish the electric light plant with all the necessary appliances. The contract price is $4,220.

PERSONAL AND MISCELLANEA.

A letter from Rome states that electric light is about to be introduced into the 11,000 rooms of the Vatican. The plant is being set up in the former barracks of the French Guards.

For years past the West End Street Railway Company, Boston, has been in the habit of giving the mayor of Cambridge 6,000 free tickets to be distributed among the city churches as a contribution to the fresh-air fund. This year the Boston Elevated Railway Company, which has absorbed the West End, gave but 1,000 tickets, and the people want to know why a company that operates above the earth is less generous than a surface company.

Octave Thanet in a letter to the Denver "Republican" from Omaha, Neb., treating of the great Exposition now in progress there, says: "But the great feature of the Manufactures Building to the general public is the electric display. This is admittedly the finest ever made at any Exposition. No one can go through it without a sensation of awe before this vast, half-unfolded terrific force which we in our generation have made the slave of our daily life. It is a wonderful exhibit—and a terrible one."

Carl Moderegger, chief engineer for Siemens & Halske of Vienna, Austria, is visiting this country to make a close study of electric street railway systems. His company is working on an elevated electric railway system for Berlin, and has the contract for a new system in Vienna. St. Petersburg and Charlottenburg are also considering proposals from his company for electric railways. In carrying on the operations of his company on such a large scale it is necessary that they be in touch with the most advanced ideas, and to get these ideas is the secret of his visit to the United States.

Koran Sugahara, chief engineer of the Kobe Railway Company and of the Buso Chuo Railway Company, Japan, is a guest at the Hotel Duquesne, Pittsburg. He left Japan on the 8th of July and reached Pittsburg on the 1st inst. His purpose is to inspect 7,000 tons of steel rails the Carnegie Steel Company is making for his road. The "Dispatch" credits Mr. Sugahara with the following remarks: "There is no city in the United States so well known in Japan when iron and steel industries are considered as Pittsburg. Your city is particularly interesting to us as a people, for our energies are all directed to the development of our country by introducing everything that is best in invention and mechanical skill. Japan looks to the United States and England for models in everything she is striving to attain. All Japan's sympathies are with these countries, and she would like nothing better than an alliance with them."

Charles Poppe, an electrician employed by the underground trolley company operating the Lenox Avenue line, New York, on Tuesday last touched a live electric wire while at work in a conduit, and though 2,000 volts went through his body he is alive to tell the tale. Poppe was called to the conduit at 135th street and Lenox avenue during the afternoon to correct some defect. He climbed into the manhole and soon completed his task. While getting out he placed both hands on the channel rail and received the full force of the current. He was picked up apparently dead, but in a few minutes he revived, and beyond several serious burns on his hands, he seemed none the worse.

Dr. George B. Richmond, a mechanical genius who was accredited by some scientific journals with having invented the telephone, died at Lansing, Mich., on the 4th inst., at the age of 49. A dispatch from Lansing in the Detroit "News" announcing the death says: "Dr. Richmond applied for a patent a little later than the Bell people, but was, without doubt, prior to Bell in discovering the principle of the telephone. The Bell people were so greatly exercised over Dr. Richmond's application that they sent an agent here to purchase his patent, offering him $10,000 in cash and a permanent salary of $2,000 per year. He was dissuaded from accepting the offer by friends, who were to raise money to push his claims. They failed to do so and the claims went by default."

Electrical Engineer Peter Wintermuth in a letter from on board the U. S. cruiser New Orleans, published in "Leslie's Weekly," gives an idea of the duties of an electrician on a war vessel. He says: "On most ships-of-war the electricians stand their regular four-hour watches in the dynamo-rooms. We do not. The steam engineering department has charge, and it is our care to look after the circuits, the instruments, and make such repairs as are necessary. A complete test of the whole plant must be made each 'quarter,' and we have just finished our first one. The current is furnished by three thirty two kilowatt generators, direct connected to Armstrong compound generators. Their capacity is 400 amperes each. When it is considered that there are motor and searchlight circuits, and that the whole system needs constant attention, it may be seen that much work is necessary to keep the system in working order. The main battery, consisting of the guns, is provided with electric firing devices and miniature incandescent lamps for night sights. This power is furnished by batteries, and beyond testing twice each day they do not require much attention. A correct and complete log must be kept daily. This includes the reading each hour of the steam pressure, engine speed, voltage and current on the generators, with any remarks as to the general working of the system during each twenty-four hours. All materials expended from the electrical store-room must be carefully accounted for. When at sea in the enemy's country a man must sleep on each fighting top for possible operation of the searchlights, of which we carry four. Our work is, of course, harder some days than others. Altogether, an electrician's position is far from being a snap. There is much disagreeable work, and it seems to a new man that the officers have unpleasant ways of saying things."

RECENT COMPANY ELECTIONS.

Laconia & Lakeport Street Railway Company, Laconia, N. H.—President, Harry L. Pierce; treasurer, Charles T. Foster; clerk, Edmund Little; directors: Harry L. Pierce, Charles T. Foster, Leominster, Mass.; George H. Cooke, Athol, Mass.; Samuel B. Smith, Edmund Little, Albert G. Folsom, Laconia, and Alpha J. Pillsbury, Tilton, N. H.

Pittsfield Electric Company, Pittsfield, Mass.—President, Alexander Kennedy; manager, W. A. Whittlesey; assistant manager, W. R. Gardner; treasurer, W. A. Whittlesey; clerk, W. L. Adam; directors: W. R. Plunkett, Alexander Kennedy, C. E. Merrill, W. L. Adam, James W. Hull, W. A. Whittlesey and H. R. Peirson.

Escanaba Electric Railway Company (reorganized), Escanaba, Mich.—President and manager, A. R. Moore; vice-president, O. B. Fuller; secretary, I. C. Jennings; treasurer, Edward Erickson; directors: J. B. Moran, A. R. Moore, J. K. Stack, M. H. Grover, Edward Erickson.

Standard Electric Heat, Light & Power Company, Avoca, Pa.—President, ex Congressman Jordan, of Tunkhannock; directors: A. H. Squiers, E. T. Squiers, Frank Tergler and Leon Schrager.

INCORPORATIONS.

The Eastern Townships Light, Power & Carbide Company, North Hatley, Can.—to supply electric light to the villages of Waterville, Eustis and North Hatley, and also to manufacture calcium carbide. Capital stock, $50,000. The company has purchased the entire plant formerly owned by Edgar & Roy and propose to extend the business.

The Mexico City Light, Heat & Power Company, New York. Capital stock authorized, $5,000,000; subscribed, $500; paid in, $50. Incorporators: Andrew L. Conary, Frank Johnson, William C. Foster, Frederick Giblin, New York City.

The Esmond Electric Traction & Signal Company, New York City. Capital stock authorized, $5,000,000; subscribed, $500; paid in, $100. Incorporators: David M. Maxon, Charles S. Jones, David A. Davies, Brooklyn, N.Y.; R. H. E. Starr, George E. Cruse, New York City.

The Mason Electric Light Company, Mason, Mason County, Tex.—to supply electric light. Capital stock, $5,000. Incorporators: L. Gugenheim, V. M. Loring, John Lemberg, Otto Donop and Richard Grosse.

The Mattoon Heat, Light & Power Company, Mattoon, Ill.—to supply electric light and hot water heating. Capital stock, $52,000. Directors: C. E. Wilson, Louis Katz, J. F. Marks, Allan McFall, J. A. Montague, G. G. McCamant, E. E. Somerville. The company has a 25-year franchise to operate in Mattoon.

The Brodhead Contracting Company, Newark, N. J.—to build railroads of all kinds, canals, reservoirs, waterworks, bridges, telephone, telegraph and electric light lines and plants, and to build, purchase and sell vessels, warehouses, etc., buy land, and deal in mortgages, bonds, stocks and all kinds of securities. Capital stock, $125,000, business to begin on $1,000. Incorporators: James E. Brodhead, of Flemington; Charles Holzhauer, of Newark; Calvin E. Brodhead, Jr., of Perth Amboy; Andrew D. Brodhead and Frederic J. Foulks, of Elizabeth, N. J.

The Berlin Electric Light Company, Berlin, Somerset County, Pa. Capital stock, $4,000. Directors: W. S. Matthews, Berlin; J. A. Berkey, G. B. Hugh, J. M. Bricker, H. F. Barron, Somerset.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED AUGUST 9, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

608,723. Electric-Arc Lamp. Thomas Spencer, Philadelphia, Pa. Filed Sept. 29, 1897.

ELECTRICAL MACHINERY AND APPARATUS.

608,685. Lightning-Arrester. John F. Kelly, Pittsfield, Mass., assignor of one-half to Cummings C. Chesney, same place. Filed Dec. 16, 1895.

608,711. Electric Motor. William H. Powell, Erie, Pa., assignor to the Keystone Electric Company of Pennsylvania. Filed Nov. 4, 1897.

608,721. Automatic Electric Regulator. Robert Skeen, St. Louis, Mo. Filed Oct. 23, 1897.

608,755. Apparatus for Storing and Using Solar Heat. Henry F. Cottle, Boston, Mass., assignor of two-thirds to William Calver, Washington, D. C., and John J. Pratt, Revere, Mass. Filed Dec. 11, 1897.

608,842. Electric Meter and Motor. Harry P. Davis, Pittsburg, and Frank Conrad, Wilkinsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed June 18, 1898.

608,878. Switch for Varying Electrical Resistance. Eduard F. H. H. Lauckert, London, England, assignor to Siemens Brothers & Co., Limited, same place. Filed Nov. 29, 1897.

608,895, 608,896. Generator for Electrical Igniters. Benjamin McInnerney, Omaha, Neb., assignor to the McInnerney Manufacturing Company, same place. Filed March 30, 1898.

608,952. Electrical Cooking Apparatus. John B. Carv, Baltimore, Md., assignor of one-half to Marie Clothilde Delavy, same place. Filed March 14, 1898.

ELECTRIC ELEVATORS.

608,789. Elevator. Charles H. Newhall, Providence, R. I., assignor of one-half to James A. McCoart, same place. Filed Dec. 9, 1896.

TELEPHONE AND TELEGRAPH APPARATUS.

608,846. Telegraph-Repeater. Henry P. Donnelly, Cincinnati, O. Filed June 23, 1897.

608,932. Telegraphy. George V. Trott, Chicago, Ill., assignor of one-half to Ella M. Cozens, same place. Filed Aug. 13, 1897.

MISCELLANEOUS.

608,614. Plate for Secondary Galvanic Batteries and Composition for Producing Same. Carl Marschner, Berlin, Germany. Filed Sept. 30, 1896.

608,637. Supporting-Clip for Overhead Electric Conductors. William A. Bartley, Boston, Mass. Filed May 23, 1898.

608,714. Storage Battery. John D. Rively, Pittsburg, Pa. Filed June 9, 1897.

608,768. Electrodynamic Apparatus for Operating Clipping, Brushing or Other Mechanisms. Warren P. Freeman, New York City, assignor to Robert J. Campbell, same place, and Francis Larkin, Jr., Sing Sing, N. Y. Filed Aug. 12, 1897.

608,906. Insulation of Electric Wires. Joseph A. Poche, New Orleans, La. Filed June 22, 1898.

608,911. Electric Cable. Henry A. Reed, Newark, N. J. Filed Oct. 24, 1896.

608,928. Apparatus for Heating Air for Therapeutic or Other Purposes. William Taylor, Edinburgh, Scotland. Filed Dec. 21, 1897.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

TELEPHONE AND TELEGRAPH.

A Detroit paper says: "Michigan farmers are taking kindly to the telephone, and it is probably but a matter of a few years when the telephone will be as common in the country as it is in the cities now. In Allegan county the farmers have an exchange of their own and they maintain it by annual assessments. The line runs from Holland, through Saugatuck, Ganges, Douglass and Fennville to South Haven, and it is used chiefly during the fruit season to facilitate the handling of berries and peaches. About 130 farmers and fruit growers built the line and maintain it, and the annual assessment upon each is about $10. Every township in Oceana county has telephone connections with Hart, the county seat, and this system is essentially a farmers' exchange, and is owned and maintained chiefly by the farmers and fruit growers. The Oceana county system, as also the Allegan county fruit growers' line, are being connected with a State exchange, and before the peach system fairly opens the farmers in both sections will be in easy talking range of the commission and railroad men here and the steamboat men at the lake ports. Gratiot county has another farmers' exchange which, with Ithaca as the center, has connections with every township and many farmers. The system gives free service throughout the county to its subscribers and will soon be connected with the outer world. It is a great advantage to the farmers in marketing their products."

A veritable network of telephone wires, says the Sioux City *Times*, will soon cover northwestern Iowa and the country in Iowa, Nebraska and South Dakota around Sioux City. In addition to the numerous toll lines which already radiate in every direction from Sioux City, the independent companies and the Bell companies now are engaged in building extensions which will cost about $100,000. W. A. Houts, a banker of Parker, S. D., and W. W. Prichard, of Spirit Lake, each a large promoter of independent lines, met in Sioux City a few days ago and conferred regarding the work of construction. Mr. Prichard has just completed his line from Sheldon to Cherokee, and is building from Cherokee to Remsen. The material for the Houts line from Sioux City to Remsen, where it will connect with the Prichard system, is on the ground. This line will be built by way of Le Mars, and a branch line will extend north from Le Mars to Sheldon, running through Dalton, Seney, Struble, Alton, Orange City and Sioux Center. Mr. Houts also will run a line west from Orange City to Hawarden. Mr. Prichard will extend his lines east from Cherokee along the line of the Illinois Central to Storm Lake, and along the Chicago and Northwestern from Sutherland to Laurens. The material for these extensions is being delivered.

The Alaska Telegraph & Telephone Company, composed of prominent San Francisco capitalists, have succeeded in securing a franchise from the Canadian Government granting them the right to construct, operate and maintain telegraph and telephone lines in Canadian territory over the Chilkoot Pass, running along the lakes and up the Lewis and Yukon rivers to Dawson City. The line will begin at Juneau, Alaska, and from there will run in a northerly direction to the town of Dyea, thence in a northeasterly direction over the Chilkoot Pass. It will then follow the line of the Lewis and Yukon rivers to Dawson City, and from there on to Circle City, where it will terminate. The company was incorporated in San Francisco in July, 1897, for $250,000. The officers of the company are Theodore Reichert, president, and J. F. Fassett, secretary. The present directors are: I. J. Truman, of the Columbian Banking Company; Theodore Reichert, late Surveyor General of California; D. E. Bohannan, George T. Gaden and J. F. Fassatt.

Rival telephone companies are about to clash in the Monongahela Valley, Pa. The Bell Company has had a monopoly in this territory, but the Maryland, Pennsylvania & West Virginia Company is now making strong competition. The latter has established exchanges at Uniontown and Connellsville, and is putting in an exchange at Masontown. The new company has purchased private lines to Farmington and Masontown from Uniontown, and is hustling to secure the right of way to Brownsville and on down the Monongahela.

The annual report of the Kansas Labor Commissioner states that there are 16 local telephone companies in Kansas operating successfully. A bitter war is now being waged between the local companies and the Missouri & Kansas Company, the Bell licensee. Commissioner Johnson anticipates that all the first and second class cities in Kansas will have their own local companies in a few years, and that a company will be formed to couple the local companies together with long distance wires.

The National Fire and Police Telegraph Superintendents' and City Electricians' Association, which held its annual meeting at Elmira last week, closed its sessions on the 11th inst., after electing officers and deciding to hold its next national convention in Wilmington, Del. The officers elected are: President, Jonathan W. Aydon, Wilmington, Del.; vice-president, C. T. MacDonald, Ottawa, Canada; treasurer, Adam Boesch, Newark, N. J.; secretary, H. T. Blackwell, Jr., New York; financial secretary, Burt McAllister, Bradford, Pa.

The Des Moines (Ia.) *News* states that the plan of the Central Telephone Company of uniting several of the smaller independent toll lines into one company has met with marked success. Already they have control of several different lines running into Des Moines and are now looking forward to a consolidation of probably the Boone or Marshall County Telephone Company. These are considered the strongest of the independent organizations.

The Sacramento (Cal.) *Bee* says: "The Western Union and Postal Telegraph Companies and the Wells-Fargo Express Company are not the only corporations doing business in Sacramento that have avoided the war tax. There is the Pacific Telephone & Telegraph Company, otherwise known as the Sunset Telephone Company, which has not only saddled its share of the war tax upon the people, but has actually profited through the enactment of the War Revenue bill."

The People's Telephone Company, which expected confidently to get a telephone franchise in Windsor, Ont., has become disgusted with the shuffling action of the council and dropped out of the contest. The local Bell company appears to have a strong political "pull" with the present council, and the People's Company has decided to wait until a new council in more accord with the sentiments of the people on the telephone question is elected.

The directors of the Tidewater Telephone Company met at Gloucester Court House, Va., on the 5th inst., and in addition to transacting routine business declared a 5 per cent. dividend. This company started in 1888 with about 100 miles of wire and 17 telephones, which were rented. It now has 266 miles of wire and 76 stations.

The New York & New Jersey Telephone Company is extending its line to the army camp at Montauk Point, Long Island. Several circuits will be laid and some of them are already completed. An exchange will be erected and expert operators placed in attendance. Special rates will be given to soldiers and to any one talking with soldiers.

Dock Jarvis of Hubbard and Tice Moreland of Rienzi, have been canvassing for subscriptions for a proposed telephone line from Hillsboro, Hill county, Tex., to Hubbard and Mount Calm, and have met with much success. The line will connect Hillsboro with Massey, Zeevee, Rienzi, Irene, Hubbard and Mount Calm.

M. F. Thompson and Walter Stuart of Carlisle, J. L. Shelly of Mechanicsburg, W. B. Oyler of Newville, and R. W. Hockersmith of Shippensburg have applied for a charter for the Southern Pennsylvania Telephone Company to operate lines in the southern counties of Pennsylvania.

A charter has been granted to the Liberty & Central Telephone Company of Liberty, S. C. The officers of the company are: President and general manager, T. N. Hunter; secretary and treasurer, H. L. Clayton.

It is announced from Rockwood, Mich., that the People's Telephone Company of Wayne and Monroe counties will extend its line next to Scofield, Maybee and Monroe.

New Companies Incorporated.

The American Telephone Directory Company, Pittsburg, Pa. Capital stock, $10,000; amount subscribed, $1,000 amount paid in, $100.

The Quaker City Telephone Company, Quaker City, Ohio. Capital stock, $500.

The Winchester & Lexington Telephone Company, Winchester, Ky. Capital stock, $1,650.

The Warren Telephone & Telegraph Company, Warren, Pa. Capital stock authorized, $25,000; subscribed, $500; paid in, $50. Incorporators: Geo. O. Chilton, E. K. Reedy, E. M. Estell, P. C. Russell, D. J. Keefe, Charleston, W. Va.

The Union Telephone & Telegraph Company, Erie, Pa. Capital stock authorized, $1,000,000; subscribed, $500; paid in, $50. Incorporators: Geo. O. Chilton, E. K. Reedy, E. M. Estell, P. C. Russell, D. J. Keefe, Charleston, W. Va.

The Moral Telephone Company, Moral, Okl.—to build and operate a line from Moral to Tecumseh, Lexington and Purcell. Capital stock, $2,000. President, J. M. Lamm; secretary, J. R. Lamm; treasurer, L. P. R. Miller.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

Abbreviations: crt. indb., certificate of indebtedness; coll., collateral; cons., consolidated; const., construction; conv., convertible; com., common; deb., debentures; exten., extension; gen., general; g., gold; guar., guaranteed; inc., income; imp., improvement; pd., paid; pfd., preferred; mtg., mortgage; tr., trust; A., annually; S., semi-annually; Q., quarterly; A. & O., Apl. and Oct.; F. & A., Feb. and Aug.; M. & S., May and Sept.; J. & D., July and Dec.; J. & J., Jan. and June.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 11¾c.; Lake, 11¾@12c.; casting, 11½@11⅝c.

The Redlands (Cal.) Electric Light & Power Company has filed a certificate of an increase of capital stock from $200,000 to $500,000.

The Third Avenue Railroad Company, New York, has declared a quarterly dividend of $2 per share, payable August 31. Transfer books close August 19 and reopen September 1.

The receivers of the Saginaw (Mich.) Street Railway have been authorized to issue $33,000 worth of additional certificates to be used in paying city taxes and building new track.

Bridge Commissioner Shea has practically decided to grant the application of the Brooklyn trolley companies for two additional loops on the bridge structure so as to relieve the traffic congestion on the New York end.

The State Railroad Commission has approved the petition of the Metropolitan Street Railway Company of New York to increase its capital stock from $30,000,000 to $45,000,000. Of the $15,000,000 increase $10,000,000 will be sold at par to stockholders at once and $5,000,000 will remain in the treasury.

The annual report of the Boston Electric Light Company for the year ended June 30, 1898, shows gross earnings of $809,943, against $759,643 the previous year; expenses $513,409, against $485,498; net $296,534, against $274,145; interest charges $70,393, against $63,242; net for stock $233,453, including $7,312 premium on stock sold, against $218,644, including $7,742 premium on bonds sold; dividends $102,000, against $110,500; surplus $131,453, against $108,144.

Superintendent of Lamps Donovan's annual report shows that Boston's street lighting expenses for the past fiscal year were $619,697.80. The total appropriation was $620,000. The salary list was $8,434.34, or only about 1⅓ per cent. of the expenditures. The total number of lamps was 13,577, of which 3,007 were in Dorchester, 2,734 in the city proper, 2,338 in West Roxbury, 2,019 in Roxbury, 1,061 in South Boston, 986 in Brighton, 738 in East Boston and 692 in Charlestown.

At a meeting of the bondholders of the Terre Haute (Ind.) Street Railway Company, at which bonds to the amount of $372,000 out of a total issue of $400,000 were represented, a resolution was passed constituting William H. Henkle, Moses L. Scudder and Demas Deming a committee to take charge in connection with the trustees of the interest of the bondholders and to have all the bonds deposited under a proper agreement. William H. Henkle, secretary of the Illinois Trust & Savings Bank, was appointed chairman of the committee.

A decision recently rendered by the Japanese Patent Bureau is of great importance to American inventors, as it decides that no foreign patent which has had prior registration in another country can be registered in Japan. This would seem to show that the protection supposed to be enjoyed by American and other foreign inventors under existing treaties does not exist, as the provisions of these treaties are wholly inapplicable to the patents already in existence, any of which can still be pirated in Japan.

The board of freeholders of Union County, N. J., on Monday evening granted a franchise to ex-Congressman John Kean for a trolley road between Elizabeth and Plainfield for $250,000. The county will spend the money to widen the county boulevard to 100 feet, making two wagon roadways and two bicycle paths for the entire distance of twelve miles. In addition to the quarter of a million dollars in cash, ex-Congressman Kean agrees to pay 4 per cent. interest on any amount in excess of that figure it costs to complete the boulevard improvement.

Announcement was officially made on the floor of the New York Stock Exchange on the 11th inst. that the Westinghouse Electric & Manufacturing Company had arranged for the issuance of $3,500,000 worth of gold debenture certificates, the proceeds to be used in paying off the floating debts of the concern. The bonds will run fifteen years and will bear 5 per cent. interest. Only $3,000,000 of the issue will be sold. These certificates will be placed without creating any mortgage on the company's assets. It is further agreed not to create any lien on the company's property. The new issue will, it is said, enable the return to the treasury as available assets stocks and bonds in various lighting and power companies associated with the Westinghouse concern, yielding an annual income exceeding one-half of the interest charges of the certificates.

A press dispatch from Chicago states that "the promoters of the movement looking to the consolidation under one management of the surface and elevated traction companies of Chicago are busy on their scheme and believe they have a better chance of succeeding than they had two weeks ago. Two obstacles are to be met and mastered before success is assured. The financing of the scheme has ceased to be a worry. The Manhattan Trust, Elkins & Widener, and certain Sugar and Standard Oil interests will care for that. The chief difficulty lies in securing the control of the Chicago City Railway Company. It pays 12 per cent. annually on its $12,000,000 of capital, is conservatively managed, and its stockholders are inclined to hold on to their stock." A later dispatch states that in a few days the details of the consolidation of the street car systems will be perfected. The consolidation was brought about chiefly, it is stated, through the efforts of Joseph Leiter, who is one of the principal stockholders of the Chicago City Railway Company. The arrangement is based upon the conversion of stock of that company into bonds of the consolidated corporation on a ratio that will give the stockholders of the City Railway Company a net profit of nearly $4,000,000.

Mayor Phelan has vetoed the resolution of the Board of Supervisors of San Francisco awarding the contract to the San Francisco Gas & Electric Company for lighting the city streets for two years. In closing his veto message, the Mayor says: "By the refusal of the board to grant to the Mutual Electric Light Company the same privilege enjoyed by their competitor the city will have plainly lost in two years $60,000 if this proposed contract stands. The Mutual Electric Light Company, however, has not accepted the action of the board as final, because it forthwith sued out a writ of mandamus to compel the board to grant it the privilege asked. On June 17 last the case was argued before Judge Sewall of the Superior Court and now awaits his decision. Should the court decide that the board had no right to refuse the privilege asked by the Mutual Electric Light Company and this contract be awarded now to the San Francisco Gas & Electric Company, the relief sought by the competing company would be futile and the city at the same time be deprived of the opportunity of making a more advantageous contract."

The semi-annual statement of the United Electric Securities Company, Boston, for the year ending August 1, compares with August 7, 1897, as follows: Interest and dividend received, $147,437, decrease $19,586; collateral trust bond interest and expenses, $106,223, decrease $13,590; net profit from income, $41,213, decrease $5,997; profit from sale of underlying bonds, $92,662, increase $52,467; surplus from the previous six months, $182,927, increase $176,119; total, $316,803, increase $222,590. Last year there was $50,672 charged off as against nothing this year, while this year $35,000 was paid in preferred stock dividends and $100,000 carried to special reserve as against nothing in 1897, leaving a surplus of $181,803 as against $43,541 for 1897. The collateral 5s were redeemed at about 4.03 per cent. over the subscription price. The price of underlying bonds sold on an average of about 87.63. If the remaining underlying bonds were sold at 67.1 the proceeds would retire the balance of the collateral trust 5s at 103. The semi-annual statement gives the total assets as $5,033,803; capital stock, $1,500,000; collateral trust 5 per cent. bonds, $3,352,000.

ELECTRICITY.

Vol. XV. NEW YORK, AUGUST 24, 1898. No. 7.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 1021 Cortlandt.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	2.00
FOREIGN COUNTRIES,	4.50
SINGLE COPIES,	10 cents

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY

THE AMERICAN NEWS COMPANY.

EDITORIAL NOTES.

Methods in Bidding that Should Not Be Countenanced.

It is a well-known and deplorable fact that town councils and lighting commissions are given to asking for bids on apparatus and appliances and then handling those bids when submitted in a way that is scarcely comprehensible to a business man imbued with an ordinary sense of justice. Because a bidder undertakes, after all bids have been submitted in good faith and published, to obtain an undue advantage of his competitors, there is no reason why a board of commissioners should abet him in his attempt and sacrifice their self-respect for the sake of saving to the city they represent possibly a few paltry dollars. A case of this nature which recently transpired in Detroit, Mich., will readily explain our meaning. The city was in need of 100 arc lamps, and accordingly asked for bids. Two bids only were received, one from the General Electric Company and another from the Adams Bagnall Electric Company. The former concern agreed to supply lamps at $20 each, while the latter offered lamps at $17.25 each. Both bids were referred to the city's electrical engineer, who was asked to report on the relative value of the two makes of lamps. This he accordingly did, stating that both lamps were satisfactory, and further recommending that the offer of the lowest bidder be accepted. The bids had meanwhile been made public, and no sooner had the representative of the General Electric Company informed himself of his rival's bid than he appeared at a meeting of the lighting commission and offered to furnish the lamps required at $17 each or for twenty-five cents apiece less than the Adams-Bagnall Company. His only excuse for making such an offer was that his company already had more than 1,700 lamps in use in that city, and was anxious to keep the business of Detroit for the sake of the advertisement. Let it be said in justice to the commission that they refused to accept his offer as being manifestly unfair to the other bidder, but instead of refusing to listen to any further proposition from him, they finally agreed to his suggestion to reject both bids and call for new ones, with the understanding that his offer of $17 per lamp was to hold good in case the new bids were not acceptable. The General Electric Company's representative then had the audacity to request the newspaper reporters present not to publish his offer, as by so doing they would give away his figures to his rival. We are not surprised at his not wanting the details of such a transaction made public.

That the representative of a supposedly reputable concern such as the General Electric Company should stoop to such means to an end is incomprehensible. On the other hand the lighting commission is decidedly to blame for countenancing any such proceedings with a view to saving $25 to a city such as Detroit on an order amounting to over $1,700. There is too much jugglery of this character going on between bidders and purchasers, especially town commissions, and the sooner it is frowned down the better it will be for the electrical industry.

* * *

How Electric Light Carbons are Dutiable.

The Board of Classification of the United States General Appraisers recently announced a decision regarding the tariff on electric-light carbons which will be found of interest to all those engaged in the electric lighting industry. According to the tariff act of July 24, 1897, paragraph 98, imported carbons were chargeable with duty at the rate of 90 cents per hundred. Prior to the above date carbons were commonly imported into this country in lengths of from 4½ to 14 inches and occasionally as long as 16 and even 20 inches. No sooner had the act of July 24, 1897, become a law, however, than foreign manufacturers began turning out carbons in lengths of 24, 29 and 36 inches each, with the evident intention of getting around the tariff act then in force. By cutting these sticks into proper lengths the importer would be getting practically two to three hundred carbons while only paying the tariff on one hundred. With a view to preventing this apparent evasion of the tariff act, the Treasury Department on October 27, 1897, issued the following instructions to the Collector:

"In order to reach an authorized decision on the subject, you are hereby directed to classify such carbons at the rate of 90 cents per hundred, according to the commercial length which existed at the time of the tariff act of July 24, 1897, so that sticks of carbon 36 inches in length would be chargeable with duty as consisting of three carbons of twelve inches each, and other lengths in proportion."

Thus the Collector divided these sticks into lengths of twelve inches each and assessed each of the fractional parts thereof as a separate carbon suitable for electric lighting at the rate of 90 cents per 100. The matter was carried before the Board of General Appraisers.

The contention of the importers was that they were specially provided for under Paragraph 98 as "carbons for electric lighting," and were dutiable as such at 90 cents per 100 without regard to any question of lengths.

On the other hand, the Government contended that, while they were not in their imported condition "carbons for electric lighting" of the commercial character and length commonly imported and known as such on and prior to July 24, 1897,

they can be mentally divided into lengths of twelve inches or less, and made dutiable in these reduced lengths by the hundred at the rate named.

Judge Somerville, who writes the opinion of the Board of General Appraisers, says that the articles are not suitable or capable of being used for electric lighting in the lengths and condition in which they are imported, but in order to adapt them for such use it is necessary to cut them up into shorter lengths, to point some of them and smoothe or grind the ends of others, and that prior to July 24, 1897, carbons of 24, 29 and 36 inches in length were not imported into this country, the usual lengths being from 4½ to 20 inches. He adds that the mere fact that at the date of the passage of the act the goods had not been manufactured or imported "does not withdraw them from the class to which they belong when the language clearly includes them." Further, he says goods must be assessed for duty as they are and not as the Collector may fix them up by some mental process, otherwise there would be no certainty in any tariff law; therefore it was illegal to assess the duty at the rate of 90 cents for every twelve inches. Under the circumstances the board decides that these goods do not come under Paragraph 98 at all, but under Paragraph 97, which provides a duty of 35 per cent. ad valorem on "articles composed of carbon." As the length of the carbons was increased with the evident intention of evading the tariff act, Congress will undoubtedly take the matter up at its next session and either pass a new act or add an amendment to the existing one.

The United States Signal Corps in Porto Rico.

The question of placing in communication the various army corps in an enemy's country by means of telegraph or telephone lines is an all-important one. Probably wires were never more quickly laid or under more trying conditions than were those strung by the United States Army Signal Corps under Colonel Reber on the landing of our troops in Porto Rico. According to the New York *Herald*, Colonel Reber landed at Guanica while the auxiliary cruiser Gloucester was still engaged in shelling the lurking Spaniards on shore, and began running a telegraph line to Yauco, a town some ten miles distant. The object of speedily opening communication between Guanica and Yauco lay in the fact that the regular Spanish telegraph line running east and west connected with Ponce where General Miles was about to land. The Spaniards, with a view to placing every possible obstacle in the way of our troops, had not only cut most of their own telegraph wires, but had destroyed all the batteries and telegraph instruments as well. The cutting of the wires was of little moment as they could readily be repaired, but the destruction of all the batteries and instruments was a very serious matter, as all the supplies which had been sent from the United States to meet just such an emergency had gone astray. Some battery cells were procured from St. Thomas, however, and necessity being the mother of invention, the other apparatus and appliances needed were made hastily and in a crude manner from scraps of brass found in a near-by foundry. How quickly and well the necessary lines were run, and how efficient the service was under most trying circumstances, may be gathered from the fact that within one hour after the fight at Coamo General Wilson was enabled to inform General Miles that the town had been taken. It was nothing unusual for the Signal Corps to be running wires while under fire, frequently being obliged to separate themselves from the troops and carry on their work without an escort, thus exposing themselves to an attack of the enemy with no adequate means for defence. In reply to a question asked by the *Herald* correspondent, on August 12, as to how the Signal Corps was getting on, Colonel Reber is credited with the following statement:

"Oh, well, we are getting along pretty well. We have 170 miles running now, are operating five circuits, communicating with general headquarters and Brookes' headquarters at Arroyo, Wilson's headquarters at Aibonito, Henry's headquarters at Utuado and Schwan's at Mayaguez. When everybody gets to San Juan by various routes we will have about three hundred and fifty miles of wire, one line running almost completely around the island and three across it."

When it is borne in mind that this 170 miles of wire was either run or placed in working order and numerous operating stations equipped, in an enemy's country, in the short space of seventeen days, the United States Signal Corps, which has been operating in Porto Rico, and especially Colonel Reber, deserves the greatest possible credit, for through their speedy and efficient work the carrying on of the campaign in Porto Rico was unquestionably greatly facilitated.

* * *

Reduction in the Capital Stock of the General Electric Company.

At the adjourned meeting of the General Electric Company, held in Schenectady on August 17, the reduction of the capitalization was effected, in spite of the opposition on the part of W. L. Putnam in behalf of the minority preferred stockholders. Mr. T. Jefferson Coolidge, seconded by Mr. Phelan, moved that the capital stock of the General Electric Company be reduced to $20,827,200, which shall consist of 182,760 shares of common stock, par value $100, and 25,512 shares of preferred stock, par value $100, the now existing common and preferred stock and the number of shares of each holder being respectively reduced to three-fifths of the present amounts. At this point Mr. Putnam moved to adjourn and await the result of Mr. Livermore's litigation. This motion was put to vote and lost. Mr. Putnam then filed a protest against the action of the meeting, claiming the vote to be illegal for the following reasons: First, because the charter did not authorize the reduction; second, because such reduction would practically take 40 per cent. from the value of the preferred stock and give it to the common stock; third, because the common shares had been largely over-issued and had remained unpaid; fourth, because there was no sufficient justification for reduction on any grounds whatever.

All objections were overruled, however, by Mr. Coffin, and the tellers announced that the motion to reduce the capital of the company had been carried by a vote of 243,141 shares to 9,800 shares. By this action the capital stock of the General Electric Company is reduced from $30,460,000 to $20,827,200. This two-fifths reduction of the holdings in the stock of this company bears us out in the claim that we have all along made that the General Electric Company was over-capitalized, and although the reorganization that has just taken place is by no means as thorough as it should be it is extremely gratifying to us, as we cannot help but feel it was brought about through the efforts of ELECTRICITY.

It is not often that one has the opportunity of beholding such a sight as was enjoyed by thousands of patriotic Americans last Saturday. To see pass in stately array ships that only a few weeks previously had been in the din of battle and had come out victorious is a decidedly novel sensation for the younger generation, and in the memory of some is only to be compared to the grand review of the troops at the closing of the Civil War. The welcome extended to the battle-scarred warships as they sailed majestically up the North River to General Grant's tomb was only in keeping with the achievements of the fleet and but partially expressed the grateful sentiment of the people.

Under the Searchlight.

Notes and Comments on Various Topics.

An electric light plant of sufficient capacity to illuminate the entire camp has been erected at Montauk, and the canvas city is now a veritable scene of enchantment at night. The boys from Santiago, who are well enough to be sentimental, like to sit up after taps and gaze upon the spectacle.

* * *

Prof. Callendar, recently of the staff of McGill University, Montreal, has designed a platinum electrical resistance thermometer capable of measuring temperature to the ten-thousandth part of a degree. The extreme delicacy of the instrument makes it a valuable aid in securing accurate observations of the temperature of lake and river waters during the various seasons of the year, as no thermometer is available for such minute measurements.

* * *

The Union Traction Company of Philadelphia is being sued by two of its former employes who were recently discharged for "conduct unbecoming employes." Who shall determine what the conduct unbecoming an employe is?

* * *

A leading Denver lawyer has been disbarred from practising in the Federal courts because of offensive language used in a brief against a judge. He is greatly surprised at this, as he only referred to his honor as "a calloused, cool, judicial liar, with the backbone of a jelly fish and the courage of a mud turtle."

* * *

From all accounts a concern in St. Louis is about to receive an order for 150 very fine motor cars for use in Japan. When completed these cars will be shipped to Kioto by way of San Francisco. The Japanese evidently think well of the electrical appliances made in this country.

* * *

A Novel Transfer System.

Reading, Pa., is in a state of revolt over the new system of transferring passengers that has been introduced on all the street car lines. On every transfer is pasted seven little faces, five masculine and two feminine. Of the former, one is bearded, the second mustached, the third side-whiskered, etc., while the distinction between the pictures of women is merely that of young and old. In the case of a man the conductor gives one glance, punches out the face that most nearly resembles the would-be transferer and hands over the ticket. That is easy, but imagine the conductor's feelings when he has to decide on which side of the dividing line between youth and age he must place women. Some painful scenes have resulted from this system, and the conductors declare that either it must be abandoned or else the cars must be equipped with conning towers.

* * *

A fender has been invented, says a New York paper, that might be used to prevent the Brooklyn trolley from breaking its own record. The fender is on wheels and is of steel, resembling in outline a chair. There are two wheels which turn independently of the trucks. Dummies have been set on the tracks and have been whirled into the chair, apparently without a jar.

* * *

An iron worker while fitting into place a steel column recently in Newark got a metal splinter into one of his eyes. He visited several physicians with a view to having it removed, but most of them feared to undertake such a delicate operation, which might result in the loss of his eye. It was finally suggested that an attempt be made to remove the splinter by means of a powerful magnet. This was accordingly done, and after a slight incision had

been made in the eyeball near where the splinter entered, it readily responded to the force of the magnet.

* * *

A NEW range-finder is about to be erected at Fort Hancock, Sandy Hook, as the instruments now located there are out of date and not to be relied upon for furnishing correct data; at least so it is claimed. Had a Spanish fleet attempted to force the harbor, however, we feel convinced it would have been stopped, old range-finder or no range-finder.

* * *

Electricity in Religion.

According to the New York *Times*, a collector of old and rare books recently came across a peculiar book bound in metal with what seemed to be an electrical appliance at one end. The volume was a copy of the Protestant Episcopal Book of Common Prayer, translated into the language of the North American Indians of Dakota.

The covers of the book had been carefully reinforced with substantial plates of nickeled brass, firmly fastened with five strong rivets on each side. At the top of each cover was an appliance for the insertion of an electric wire.

According to the story told by the seller of the book, the work was used in its present form by a missionary to the Indians in connection with an electric battery. While the unconverted brave whose soul the missionary desired to save held the prayer book with his hands on both covers, thus forming an electrical circuit, the latter would surreptitiously turn on a gentle current, which sent mild but appreciable thrills through the frame of the savage. These he believed to be manifestations of the newly-found religion.

We wonder how many savages were converted by this method.

MEETING OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Delegates to the Jubilee Meeting of the American Association for the Advancement of Science began to arrive in Boston as early as the 18th inst., and by the morning of the 22d most all of them were on hand. The representation this year is the largest ever present at one of the meetings of the Society. Previous to the general session at 10 o'clock on the 22d, in the Institute of Technology, a meeting of the Council was held and over two hundred new members were elected into the Association.

The local committee had perfected the arrangements for the whole meeting, and provided each member with an elaborate guide book and much information concerning the chief places of interest in and around Boston. They also arranged for the accommodation of the guests of the Association in an admirable manner. Boston received the members of the Association as a royal host and outdid herself in endeavors to cater to the enjoyment of her guests.

The city officially regards this semi-centennial meeting of one of the foremost societies in the New World as among the most important ever held in its precincts.

President Wolcott Gibbs called the opening session to order at 10:30 A.M. Prayer was offered by the Rt. Rev. William Lawrence, Bishop of the Diocese of Massachusetts.

The most noteworthy features of the programme of the morning's session were the addresses of welcome delivered by His Excellency Roger Wolcott, Governor of Massachusetts, Mayor Josiah Quincy and President James M. Crafts of the Massachusetts Institute of Technology. Désiré Charnay, in behalf of the French Government, spoke of the bond of sympathy existing between the two peoples. His address was in the French language, but was received with prolonged applause and much enthusiasm.

Governor Wolcott was in fine voice and by his masterful delivery held the rapt attention of his audience throughout. Among other things he said:

"It is with far more than ordinary pleasure that, on behalf of the Commonwealth, I extend a most cordial greeting to those who are present here to-day. The American Association for the Advancement of Science on this its fiftieth anniversary has done well to return to the soil of the Commonwealth which was the place of its birth, and which gave to it its charter. I welcome you all—those who come from the many cities of our country and those who come from foreign lands. The Commonwealth is honored by your presence. As seekers after truth you have devoted your lives to following the footsteps of science whether her majestic way is across continents, following the pathway of stars, or whether she delights to follow the minutest particles revealed by microscopic research."

Governor Wolcott then described at length in an eloquent and scholarly manner the many benefits coming to the world by the researches of men of science, and compared them to the men who have erected lighthouses on the coast, guiding and directing the course of those who will come after them. He spoke of the infinite possibilities of science, and said that in spite of the great advances that have been made, little is known to day of the mysteries of nature, so elusive is its touch.

Mayor Quincy was next introduced, and after referring to what the American Association for the Advancement of Science had accomplished, welcomed it to Boston in the following words:

"I heartily congratulate the American Association and welcome it back, after fifty years, to the scene of its birth, and extend thanks and welcome on behalf of the city of Boston to each and every one of its members in view of this meeting here, and the work which the Association is yet to do in the first half of the century to come."

President J. M. Crafts of the Massachusetts Institute of Technology then welcomed the Association on behalf of the Institute, and among other things said:

"Scholars who have walked the fields with Gray and Agassiz, who have learnt their mathematics from Peirce, their anatomy from Wyman, or their chemistry from your retiring president, might look the world over without finding leaders better fitted to guide them to the innermost chambers of scientific knowledge. In this place it is most fitting to mention the chairman of the first meeting of this Association, William B. Rogers, who was a born educator. He loved science for its own sake. His later years were devoted to the Institute which he built up, and which, now largely grown from small beginnings, has the honor of welcoming you this day; and it was on this stage that he fell, an unfinished sentence on his lips, giving his life to the cause which overtaxed his strength."

In retiring, President Gibbs introduced Professor Putnam of Harvard University, the President elect, who on taking the chair was received with vigorous applause. He said that in accepting his charge he felt overwhelmed as with one of the greatest honors that could be conferred upon him. He paid a fitting tribute to the founders of the Association, the officers who had directed its affairs, and others connected with its management. He urged scientists to join the Association in order to broaden their knowledge of science in general, and profit by intimate acquaintance with men of other branches.

Upon the adjournment of the general session the meeting was divided into nine sections in order to specialize the work of the Association in the different departments of science.

During the week a large number of important papers are to be presented dealing with almost every branch of science, there being a number especially on electrical subjects which should prove of material value.

Part Played by Electricity in the War with Spain.

In the New York *Sun* of August 21 there appeared a very interesting article on the naval lessons taught by our recent struggle with Spain. One of the officers of the battleship Texas is credited with making the following statements:

"Electrical appliances on the modern war-ship and in the various auxiliaries of up-to-date warfare, cannot be said to have had a fair trial as yet. Certainly they have not been of any great use in either of our big sea fights, although this is not saying that they might not be of the greatest importance under other circumstances. Before war was considered a serious possibility, eminent electricians made forecasts of many new, strange and valuable uses to which electricity would be put in the next contest between civilized nations.

"Ships were to be blown up while sailing over mine fields unconnected by wires with shore battery. They were even to photograph themselves on a chart in the shore room of an operator, who would then send a direct current to the mines through salt water. Torpedoes were to be projected through the air to drop on a ship and destroy it. Electricity was to be their propelling as well as their guiding force. Now, what of all this has been realized? What have we learned of mines and torpedoes? About all that is practical as the lesson from the mines in Santiago and Guantanamo harbors, of which the one on our deck is a specimen, is that submarine mines ought to be taken up and inspected at least once a month to keep them efficient. Otherwise, in tropical climates at least, mines will be so injured by general fouling and the contact pins so overgrown with barnacles that the whole thing will be useless and harmless. Not a torpedo has been exploded in the course of the war, and the attempts of the Spanish torpedo boats to get near our vessels were so quickly frustrated by the use of the searchlights that this arm of naval warfare for which so much was prophesied may be pronounced practically barren of results.

"It is in the operation of the searchlight, by the way, that electricity seems to have been of the greatest practical benefit. In blockading work, such as has principally occupied the American squadron off Cuba, the usefulness of the searchlight in guarding harbor entrances and sweeping the shallow inshore waters where light-draught vessels may otherwise slip by unobserved, has proved of the greatest value. When Admiral Cervera was bottled up in Santiago harbor the Texas and the Brooklyn or some other of the fleet kept their searchlights playing on the narrow harbor entrance every night, and it would have been an impossibility for the Spanish commander to sneak out under cover of darkness, as some of his critics have suggested he should have done.

"The electric searchlight may be put down on the list as one of the modern improvements which have really a practical value in war. One of the Brooklyn's turrets has been operated by electricity instead of by steam or hydraulic power, as the turrets of the Texas are, but we have not yet heard any report as to whether this motive power was found to possess any advantages or not.

"It is a striking fact that the carefully contrived range-finders and other delicately poised appliances for improving the accuracy of a ship's fire seem to have been forgotten in the heat of the conflict. So far as I have heard, the guns of the Oregon were sighted and fired in the old-fashioned way. I know that those of the Texas were, for the simple reason that our guns are not fitted with range-finders. We used the stadimeter to determine the range and sighted the rapid-firers just as used to be done with the old-style gun. And yet I think that for accuracy of fire the work of the Texas's gunners left little to be desired. This, of course, is not saying that the range-finder is not a most useful instrument, especially for long-distance work, but merely that it was not brought into play in the Santiago fight, nor in the battle of Manila, which was fought at even shorter range."

DUCRETET ON HERTZIAN TELEGRAPHY.*

In a lecture delivered before the Société Internationale des Electriciens on June 1st, M. E. Ducretet describes a new arrangement of apparatus for automatically printing messages in the Morse code. This has, of course, already been done by Marconi, Slaby and others who have worked at this subject, so that Ducretet's improvements are only in the details of the apparatus.

M. Ducretet gives a short account of the discovery of electric waves and their practical application to telegraphy without wires, in which the work of Marconi is scarcely mentioned, and much prominence is given to the discoveries of other inventors, chiefly French and Russian, that we do not hear much about in this country. According to Ducretet, Sarasin and de la Rive were the first to show that the efficiency of a Hertz oscillator was considerably increased by causing the spark to pass through an insulating liquid instead of air.

It is to Prof. Popoff, of St. Petersburg, however, that Ducretet gives the credit of being the first to discover telegraphy without wires in 1895; Marconi's discovery having been made in the following year. We do not intend to discuss these rival claims, but give here only the opinions of M. Ducretet.

Prof. Lodge in England, and MM. Le Royer and Berchem of Geneva, have since 1893 successfully employed Branly's tubes with filings instead of the Hertz resonator for detecting the presence of electric waves generated at a distance.

In 1890 Branly first showed the action of electric radiations upon discontinuous metallic substances such as filings, free or agglomerated in an insulating substance, and comprised between two conductors forming a circuit containing a battery and a galvanometer. These substances, originally insulators, or at least of very high resistance, became conductors when they were struck by an electric wave; and, besides, their conductivity was annihilated by a shock, only to reappear again when struck by another electric wave. The galvanometer placed in the circuit of the tube of filings deviated very strongly when the tube of filings was struck by an electric wave, and then returned to zero when the initial resistance was restored by a shock.

Branly has given the name of radio-conductors to his tubes of filings, a name which is intended to recall the fact that the conductivity of these tubes is established by electric radiations emanating from a spark. The sensitiveness of these detectors is very great, and they detect electric disturbances at a distance, even across partitions and walls. If the galvanometer is replaced by a sensitive telegraphic relay, we are able to produce in a local circuit energetic actions whose point of departure is the electric wave transmitted through space by an intermediary medium, the ether, which propagates electric vibrations from the spark transmitter in the same way as it propagates luminous vibrations.

We have thus all the elements necessary to the realization of Hertzian telegraphy; if the sensitive relay controls the electro-magnet of a recording apparatus, and long and short emissions of electric waves can be produced at a distance, then a message can be sent by the Morse code. The relay also controls the electro-magnet of the tapper which acts upon the filings of the radio-conductor. Each wave will thus be followed by a shock, bringing the radio-conductor back to its initial resistance. In practice the power of the transmitter will be adapted to the distance to be traversed.

The apparatus described and realized by Prof. Popoff in 1895 was constructed as follows: To record the electric waves produced by atmospheric electric disturbances at a great distance, he employed an instrument of the Morse type. Since 1895 Popoff has shown in various publications that his apparatus might be practically employed by the Marine for the transmission of signals. To augment the sensitiveness of his apparatus, Popoff connected one of the electrodes of his radio-conductor to a metallic wire, insulated, and fixed vertically along a mast. The other electrode was put to earth. This same arrangement may be applied to the spheres of the spark transmitter.

The insulated conductor of the receiving apparatus is a veritable collector of the electric waves launched into space; that of the transmitter plays the role of a radiator. Their length ought to correspond to the distance to be traversed.

The organs of the system of wireless telegraphy invented by Popoff may be shortly enumerated as follows: Electric waves emitted by the oscillator-transmitter; a Branly radio conductor which becomes conducting when struck by an electric wave and closes the local circuit of the relay which works the recording apparatus of the receiver; an electric tapper which acts automatically on the filings of the radio-conductor. Under the action of the shock of the tapper the conductivity of the tube of filings disappears, and recovers its original state till a new electric wave strikes the sensitive tube.

Ducretet's apparatus which he showed to the Society contains several improvements on the apparatus of Popoff. Like all telegraphic apparatus it consists of a transmitter and a receiver.

The transmitter comprises a powerful Ruhmkorff coil. In the circuit of the primary wire is a vibrating interrupter with a quick break, or a continuous rotary interrupter according to the power of the coil. A special key produces the long and short emissions of waves. A battery of accumulators furnishes the electric energy.

It is this electric energy due to a current of a considerable strength, but of only a few volts EMF., which is transformed in the secondary coil into a current of very high EMF., in the coil used in these experiments, 200,000 volts. After this transformation the electric energy does not exceed 60 watts, say one-twelfth of a HP. This heightened EMF. produces sparks which play between the spheres of the oscillator.

This oscillator is formed of several spheres between which play intermittent sparks produced by the operating key. The central spheres are plunged in an insulating liquid, and the oscillating sparks play between them. This oscillator is constructed according to the data given by Prof. Righi, but Ducretet's arrangement insures a rapid control of the length of the sparks.

From this oscillator the electric waves start which act at a distance upon the receiver.

The receiver comprises: 1. The Branly radio-conductor with its automatic tapper arranged according to Popoff. Ducretet's model has a device for regulating the position of the cylinders between which the filings are placed. The action of the external air on the filings is prevented by making the cylinders a good fit.

2. A mast with an insulated wire (Popoff's collector), and an earth connection to one of the electrodes of the radio-conductor as already described.

3. A very sensitive telegraphic relay putting in action both the electro-magnet of the recording instrument and the electro-magnet of the tapper.

4. Recording instrument. In Ducretet's arrangement the working is automatic, and allows the telegraphist to be dispensed with. This point he considers of great importance. The first wave that arrives starts the ribbon, and when the waves stop the ribbon stops.

Popoff has sent messages over a distance of 5 kilometers at sea, with a vertical conductor 18 meters in height. Marconi has traversed a distance of 16 kilometers with a vertical conductor 30 meters in height. Experiments made recently with Ducretet's apparatus show that these records can be beaten.

It is not necessary to conclude from these experiments that Hertzian telegraphy without wires will replace ordinary electric telegraphy, or optical telegraphy; but from the results attained it is possible to see the service it may render in communicating between ships, and between ships and the coast, and for military and exploration purposes. M. E. Aimé is about to test wireless telegraphy as a means of communicating between balloons and the earth.

Branly has recently shown that a battery of 12 accumulators may be put in circuit with a powerful radio-conductor, and that the current may be raised from zero to 20 amperes when the tube is struck by electric waves.

With a special kind of relay (*un electro aimant à déclic*) Ducretet was able by means of electric waves sent from a distance to (1) make a long metal wire incandescent; (2) start an electromotor; (3) excite a powerful electro-magnet; (4) illuminate a row of incandescent lamps; (5) explode a mining fuse.

* From the *Electrical Review*, London.

Magnetization and Length.

The small changes in length produced in a bar by magnetism have been investigated by many experimenters. Mr. J. S. Stevens, however, is, we believe, the first to use interference methods for measuring the changes so produced. He describes his experiments in a recent number of the *Physical Review*. The "interferometer" has now become so well known that it will not be necessary to describe it again. This instrument was used with slight modification of its construction. The mirror frame, which is commonly attached to the movable bed was removed and firmly screwed to the end of the rod to be tested. The other end of the rod was made fast to a brass cylinder, which could be moved backwards and forwards, and thus provide the adjustment usually afforded when the mirror is moved by means of a micrometer screw. The magnetizing coil was supported so that adjustment in two directions was possible. The whole was attached to a heavy wooden frame and little or no inconvenience was caused by vibrations in the building.

The magnetizing coil was composed of 15 layers of No. 25 copper wire, and was 21 cm. long. It had a resistance of 420 ohms. Current was afforded by a storage battery of 110 volts. The rods were 30.5 cm. in length and 0.953 cm. in diameter. Tests were made with wrought iron, cast iron, steel, copper, brass, nickel and aluminum. In conclusion, the author claims the following as the points of advantage of the method: Since the mirror is practically a part of the rod, little or no annoyance due to vibrations of the building was experienced; the measurements are direct and the unit so small that the error need not exceed 1 per cent.; the errors liable to occur in any mechanical device, such as the use of levers, indicators and the like, are eliminated; any auxiliary effects, such as distortion, are closely seen.

Electrical Governor for Marine Engines.

To prevent the engines of a vessel from racing when the screw rises above the water, Sig. E. Putalo has invented an electrical regulator. It consists, according to *Industries and Iron*, of two vessels of mercury, connected at the bottom by a tube, and mounted fore and aft in the ship. The vessels are about half full at normal depth. When the ship pushes forward so as to raise the screw the rods connected with the resistance are submerged one after the other so that an electromagnet is brought into play, the whole resistance being short-circuited when the screw is quite out of the water. The electromagnet operates a throttle valve in the main steam pipe, which is thrown open by another magnet. By this arrangement the steam is turned off and on. From experiments it has been shown that the mercury vessels need not be more than 34 inches apart on a ship 300 feet long.

COMMERCIAL FORMS OF ELECTRICAL RESISTANCES USED FOR LIGHTING AND POWER PURPOSES.*

BY L. B. ATKINSON.

In the early days of electrical engineering, when telegraphy was the leading branch of the science or industry, "resistance" as a property of the electric circuit had very important functions, and from the property of circuits that the resistance is proportional to the length of the conductor, in the case of faults occurring on telegraphic lines it became a means of increasing the distance from the end of such fault. And for such purposes, therefore, standards of resistance were used which were carefully calibrated, and the primary value of such resistances rested in their accuracy. Such for telegraphic purposes is still the case, but the growth of the use of electricity as a means of transmitting and distributing light and power has given rise to the use of resistances for quite other purposes, and having other requirements than that of representing an absolute or accurate value, and it is to these resistances that the present paper is devoted.

The current in an electric circuit is defined by Ohm's law; that is:

$$\text{Current} = \frac{\text{Electromotive force}}{\text{Resistance}},$$

so that for most purposes the EMF. is fixed, the resistance of the circuit is the variable by which the current is to be controlled. And thus for almost every conceivable use of electricity for lighting or power purposes, resistances are used as controllers or regulators of the current.

The functions of a resistance being primarily to regulate or determine the amount of the current, which it does by its resistance, its second function is to dissipate the heat produced by the electric power expended on the resistance. This becomes a matter of cooling surface, and leads to a wide range of possible designs.

Speaking generally then, in considering electrical resistances, the points to be considered are the (1) material of which the electrical resisting circuit is composed, (2) the nature of the support for such circuits, and (3) the material for insulating the circuit from the support, and in addition the nature of the switching mechanism for varying the amount of resistance in circuit.

(1) MATERIAL OF WHICH THE ELECTRICAL RESISTANCE CIRCUIT IS COMPOSED.

Since all conductors offer resistance to the passage of the electric current, any conductor may be used as a resistance. The following table shows the resistance of one centimeter in length of various metals and alloys, carbon and liquids, the cross sectional area of the specimen being one square centimeter and the temperature 0° C.

TABLE I.—*Specific Resistances.*

	Resistance per cubic centimeter.	Percentage variation per degree centigrade.
Silver	1.594 microhms.	.377
Copper	1.598 "	.388
Iron	9.716 "	.458
German-silver	20.93 "	.08
Platinoid	51.0 "	......
Manganin	52 0 "	Practically nil.
Eureka	60.0 "	" "
Rheostene	100.0 "	" "
Carbon	4200-40000 "	— .2
Relugite	8.2 to 8200 ohms.	— .2
Solution of soda, 10 % solution	11.5 ohms.	......
Solution of zinc sulphate, density 1.405	28.3 "	.....
H_2 SO_4 density 1.10	1.37 "	— 1.7

This table is only to be used as a guide, since, except with pure silver and copper, all the other materials are of somewhat undefined composition, and the resistance of alloys and carbon varies greatly with their chemical and physical condition. It will be observed that several of the materials used are special alloys, for the most part of nickel and manganese, which, in addition to having a very high resistance, have a very small temperature coefficient, which is important, as resistances are often worked to a temperature of 200° C., causing a very considerable variation of resistance.

An interesting example of this is in the use of iron wire when it is approaching a red heat, in which case it will be found that the resistance rises so rapidly that a very large increase of EMF. will only cause a very small increase in the current, because as the EMF. is raised, causing a small increase of current, this raises the temperature so that the resistance rises almost as fast as the EMF.

The writer some years ago used this property for arc lamp resistances, when even if the lamp was cut out the permanent rise in current was quite small.

The metals, solids and liquids shown in the table are those which are most frequently used for making resistances, and with regard to these the usual form of the metals and alloys is in the shape of wire or strip, the former generally wound into coils.

Carbon may be used either in rods, in which case the ends should be electro-coppered and the connections clamped and soldered to the copper, or the carbon may be used in the form of flat plates piled on one another.

The material "relugite," shown in the list, is a new material now being put on the market by the Electric Insulation Syndicate of Cardiff, and having an incombustible base, such as asbestos, in which is deposited conducting carbon, and the specific resistance of which can be made as required within the limits given, and this material also may be used either in strips, the current passing from end to end, or in plates or layers through which the current passes.

Liquids are used generally where high resistances are required, and are on the whole an unsatisfactory form of resistance, as the solutions creep and cause loss of insulation on the circuits to which they are attached, whilst the liquids also leak or evaporate, so that they have to be made good, and the composition and resistance are constantly varying.

Carrying Capacity of Resistance Materials.—It is important to determine what is the carrying capacity of the wires, strips or plates of which a resistance is composed; this being defined in relation to some particular allowable rise of temperature. The rise of temperature to be allowed is probably the point on which the greatest difference of opinion seems to exist among manufacturers.

It is somewhat curious that the fire insurance offices, who define to a nicety the insulation of the circuit and other quantities, are exceedingly vague on what is probably one of the chief fire risks that are run, most of the offices satisfying themselves by merely stating that the resistance should be constructed of and mounted upon incombustible material, and that no combustible material should be within a foot of the resistance.

Since most organic matters and fabrics char at a temperature of 200° C., the writer thinks that that limit at all events should never be passed, and probably the rule defining that the maximum temperature of the hottest part at the maximum working load should not exceed 150° C. would be a safe rule.

The principal methods of dissipating heat from resistance are by radiation, air currents, and in certain cases by circulating liquids such as oil or water.

The amount of heat radiated at the temperatures discussed is not large, and the use of liquids for cooling is not common, so that practically speaking cooling by air or currents is the usual method.

It is obvious therefore that the design should be such as to allow a free circulation of air through those parts where the heat is being produced.

Wire Resistances.—For this reason where wires are used it is advantageous that the diameter of the wire should be small, so as to give a maximum surface for a given cross sectional area, and to carry the requisite current a sufficient number of wires should be placed in parallel.

Again, where wires are wound into coils, these coils should be open, and there should be a space between successive turns of the coils of 2 or 3 diameters to allow an effectual passage of air.

In the case of long coils placed vertically, the upper parts of the coil become far the hottest, as the air heated by the lower coils is the only cooling medium.

It is almost impossible to give any general rule as to the carrying capacity of wires in coils.

If the wires are in coils drawn out so that the space between the wires is about 2 diameters, the current the wires will carry for the same temperature will be about one-third of that given by the diagram.

One of the most effective forms in which wire can be used is in the form of wire gauze, and the best class of gauze is that in which the longitudinal wires carry the current, the wires all being in parallel connection, whilst the cross threads carry away the heat, and in this case the load to be carried by a given wire is double that given in the table.

A great difficulty occurring with wire resistances, particularly where alloys, such as german-silver, are used, is that the wires become brittle or rotten and break, causing short circuits and danger of fire.

In the case of resistances enclosed in boxes so that only the outside surface will dissipate the heat, the carrying capacity of the wires is much less than that given in the table, and the ultimate carrying capacity of the resistance will depend on the surface of the casing exposed to the air, and for a temperature of 150° C. the total external surface should be about 10′′ per watt to be dissipated.

The surface for this purpose may be increased, if of metal, by casting ribs or fins upon the casing so as to increase the surface.

Some resistances are only required for a short time at intervals, such, for instance, as resistances for starting motors, and here the element most to be considered is not the surface on which depends the power of steadily dissipating heat, but the total specific heat of the parts on which depends the rise of temperature with the given load in the time for which it is to be used, and in this case materials having a high specific resistance with large bulk may be used to advantage, or if fine wires are used they may be imbedded in material such as enamel or sand or asbestos which will absorb by conduction the heat from the wire itself.

Carbon Resistances.—A common form of carbon resistance consists in the use of ordinary lighting pencils with the ends coppered and connected up by clamps.

These resistances for testing purposes can be run at a very high temperature, but they dissipate heat badly, they are very liable to come broken, and are not often used for resistances which may have to be transported.

Carbon resistances made up of plates placed in a frame are often used, and they have the advantage that the resistance may be varied by screwing them up more or less tight by a clamping screw.

In this case a very large part of the resistance is due to the resistance at the surface of contact between the layers, and due also to the fact that the current travels in the plane of each layer from the points of contact at the surface of one set of plates to those of the next set; these, in most instances, not coming opposite to one another on the plates.

In other words, except when the plates are screwed up quite tight, the current is traveling by a zigzag course through the pile of plates, and it is principally this which enables the resistance to be varied.

The material previously mentioned, viz., "rel-

* Paper read before the Northern Society of Electrical Engineers at Manchester, Eng.

ugite," is used in the same way, and with the same results, but it has a great advantage over the carbon resistances in that the material being flexible and elastic, a much wider range of the screw is obtained, so that the resistance can be varied more gradually, whilst the tendency with solid carbon resistances for the plates to actually break contact, and so set up an arc, is got over.

The chief difficulty with carbon resistances is that they present a very small cooling surface.

This difficulty has been obviated in the case of "relugite" resistances by interposing metal plates between the plates of material, which metal plates are larger than the plates of the material, and thus serve to conduct the heat from between the plates, and to present a large surface for the air to pass through to cool them.

Liquid Resistances.—The commonest form of liquid resistance is a wooden tub filled with water in which is sulphuric acid, common salt, washing soda, or other metallic salt, to render it more or less conductive, and in which are immersed plates leading in the current.

Such resistances cannot, of course, rise above the temperature of boiling water, and they absorb a large amount of heat due to the large latent heat of steam.

Such an arrangement is of course a very rough one, and only used for temporary purposes.

For permanent installations iron or earthenware jars or pots are used, containing solutions, and having electros of various forms which can be moved in relation to one another.

(2) MATERIALS FOR SUPPORTING RESISTING WIRES OR MATERIALS.

In the early days of the use of electric power, resistance wires or coils were usually strung in wooden frames (see Fig. 1), and the writer believes he was

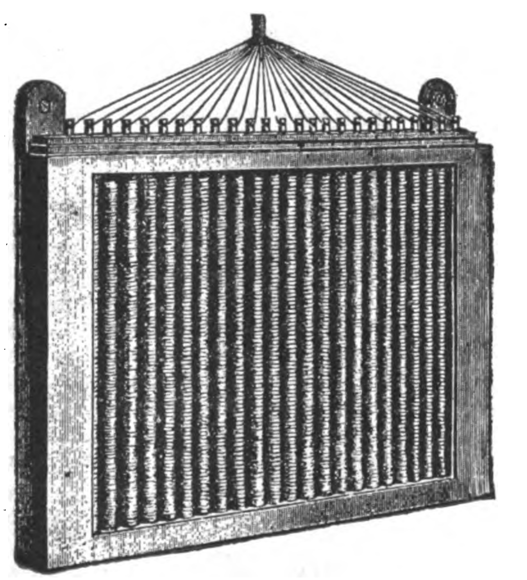

FIG. 1.

the first to introduce into the market standard patterns of resistances in which the supports were wholly composed of incombustible material—that is to say, iron frames carrying slate or porcelain insulating parts to which were attached the resisting wires—and Figs. 2 and 3 show designs which were registered by the writer in 1887, and large numbers of which were made by the writer's then firm.

These designs, slightly modified, have been largely adopted by different makers and are now on the market, all embodying the same important point of fireproof insulating supports for the wires.

These resistances may be, and usually are, provided with a switch having a number of contacts, which enables, more or less, the resisting wire to be included in the circuit.

A class of support previously mentioned is the use of enamel on a base of iron. In this case the iron is first enamelled, to give it an insulating coating; the wires, which are very fine, are then placed on the enamel, and covered with thick coating of enamel, which is then fused, so that the wires are formally imbedded in it.

The resistances known as the Carpenter resistances, and the resistances in most heating and cooking apparatus are arranged in this manner. In this

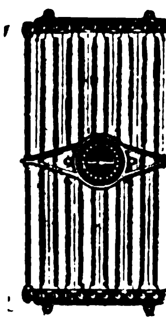

FIG. 2.

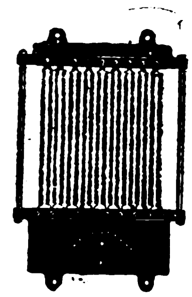

FIG. 3.

case the enamel carries the heat from the wire to the iron support, which then distributes it, and forms the cooling surface.

In the case of the "relugite" resistance material, this is carried in iron frames, generally on pillars or bolts passing through it, the insulation being enamel, and in certain cases mica or asbestos sheets are used where flat surfaces are to be insulated.

NOTES ON THE ELECTRO-CHEMICAL TREATMENT OF ORES CONTAINING THE PRECIOUS METALS.*

BY MAJ.-GEN. C. E. WEBBER.

The precipitation of gold and silver with the aid of an electric current has a history which may help my audience—many of whom, I think, are more or less acquainted with the subject—to appreciate the present situation of a question which cannot be devoid of interest to our Institution.

If we go far enough back in the subject, we shall find that in 1835 to 1840 Becquerel used a saturated solution of common salt for dissolving compounds of silver and lead, and subjecting the solution to the electric current, both to hasten the reactions of the process and better to utilize the precipitating agent.

In 1843 Prince Pierre Bagration described in the *Bulletin de l'Academie des Sciences de St. Petersbourg* some experiments with finely divided gold dissolved in an aqueous solution of potassium cyanide under the influence of the galvanic current, by which means he precipitated the precious metal on a copper cathode.

In 1867 Julio H. Rae proposed, in the United States, a method of treating ores containing gold and silver mixed with a suitable solution, such as one of cyanide of potash in water, by the action or aid of a current of electricity; suggesting at the same time in addition, the agitation of the solution.

Although Rae's proposals are said to have never gone beyond an experimental stage, in his description is found the combination of (1) a circular vessel to contain the ore; (2) a solvent in solution; (3) a stirrer, or agitator, on a vertical shaft, working with a rotatory motion within the vessel, the stirrer being connected with one electrode, and a conducting metal plate which supports the charge under treatment within the vessel being connected with the other electrode, or a source of electricity.

In December, 1882, Messrs. Breakell and Haycraft patented, in South Australia, a means of treatment of slimes by agitation combined with an electrical current and amalgamation. In nearly all respects they copy Rae, except that they use no solvent of the precious metals present in the mixture under treatment.

In their apparatus (Fig. 1), A is the vessel, or "pan," in which the operation is performed. B is a revolving shaft, carrying arms or rakes, C, C, which is connected by a contact, preferably of mercury, on the top of the shaft, with the positive pole of a battery. The bearing on which the axis revolves is insulated from the vessel. D shows the position of a pulley on the shaft by means of which it is revolved. The negative pole of the battery is connected with the vessel, which is of iron, or such suitable material; so that the vessel itself, as well as the mercury lying at the bottom of it, constitutes the cathode.

In passing, I must mention Barker's apparatus of 1882, for extracting gold and silver from "sands" containing them, in which we find the use of a mercury cathode, combined with stirrers on horizontal shafts which however did not constitute the anode.

Also Body's process of 1883, which combined a drum and ball crusher of ore containing precious metals. These had been previously ground and dissolved in a solution containing ferric salt. The axle or the revolving drum carries carbon anodes, and the walls of the vessel and the balls serve as cathodes, on which the noble metals after solution are deposited electrolytically. Mercury is used, but only for the purpose of collecting the free gold and silver.

I propose to avoid as far as possible allusion to the large number of inventions which deal chiefly with electrical amalgamation, but it is difficult not to refer to some of those which use electrical deposition. Thus, when, in 1888, MacArthur and Forrest investigated the chemistry of, and patented their world-renowned process, they seem to have neglected, or, having tried it, discarded, the assistance of electricity in combination with a weak solution of potassium cyanide, because of a greater expenditure of chemicals which they alleged to be the result, and also because they believed it encouraged the solution of any baser metals together with the gold and silver which might be present in the ore, and involved the extra expense of their separation.

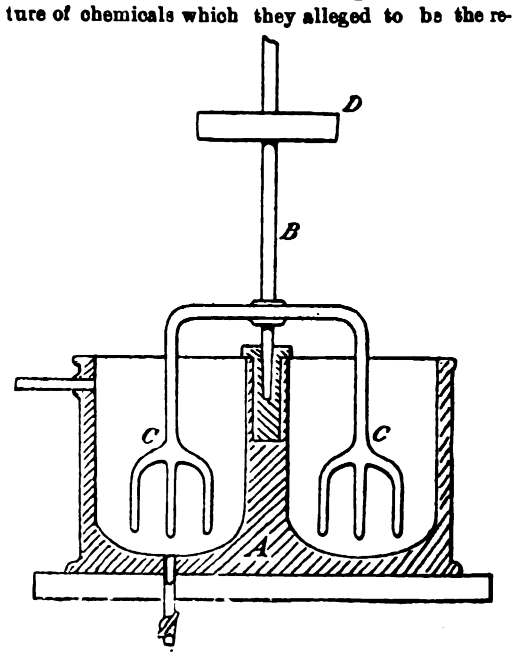

FIG. 1.

I need not here refer to the reasons for MacArthur and Forrest's rejection of electricity, nor to the well-known Siemens & Halske process,* in which "circulation" of the solution by gravity is an essential feature, as I wish to direct your attention more particularly to those processes in which the combination of similar conditions with "agitation" are included.

Following on Rae and Breakell, in 1891 Hannay described and patented in the United Kingdom a process and an apparatus for "extracting gold from minerals containing it, by subjecting the finely pulverized mineral mixed with a solution of cyanide to electric action and agitation in the presence of mer-

* Paper read before the Institution of Electrical Engineers, London.

* In 1896 added to, if improved on, by Stuart Croasdale. See *Engineering and Mining Journal* of 12th December, 1896.

cury." In this process—which it is not understood was ever put to work on a practical scale, and which it is believed, in common with his predecessors', is not described so that the ordinary intelligent engineering mind could erect the apparatus and work it successfully—there is found the combination of (1) a circular vessel or tank; (2) an electrolyte consisting of a solution of cyanide of potassium, mixed with pulverized ore; (3) a stirrer, or agitator, on a vertical shaft, standing in the middle of the vessel, and acting by rotation on its axis; (4) one electrode—the anode which in this case is a cylindrical block of carbon—being suspended or fixed in the middle part of the vessel. Two examples of the apparatus were published in December, 1891, and in one of them (the later one) we find another condition in combination with the above, which, so far as I can discover, but for the proposal of Breakell and Haycraft, in 1882, would be the first example in which the bottom of the vessel described as of "basin shape, containing mercury," as in the case of the ordinary amalgamating pan, is also the cathode. Examination of the description of this cathode will, I think, not satisfy electricians of its practical value without important modifications. The use of solvents or

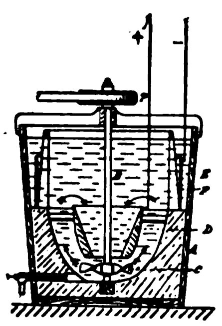

FIG. 2.

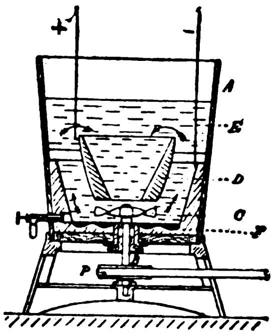

FIG. 3.

oxidizing agents other than potassium cyanide is not proposed, and the strength of the cyanide solution, current, etc., is not given.

There are two forms of this apparatus (see Figs. 2 and 3). In each there is a cylindrical vessel, A, with a revolving vertical shaft, B, turned by a pulley, P. The shaft carries what is called a "propeller," which serves only for the purpose of stirring the liquid contents of the vessel. In each section a hollow cup-shaped block, D, of carbon, is shown, which constitutes the anode, and is connected with the positive conductor from a dynamo. In the example No. 3 the cathode—which is formed of carbon plates, F, within an annular frame, F—is fixed above the propeller. In No. 4 the cathode is a body of mercury which lies in the "basin-shaped" bottom of the vessel.

There exists an interesting description of a process patented in 1893 by Mr. Molloy, M.P., who, between 1884 and 1887, had dealt with the subject in a different manner. Although it does not include all the features of treatment to which I wish to confine myself, its chemical reactions are not without interest to our subject. It involves at first sight two stages, but really it has four, namely :

First, the solution of the gold contained in a pulverized ore by means of bromine, chlorine, cyanogen or other compounds; secondly, the charging a mercury cathode, which forms the bottom of a treatment tank, electrolytically, with potassium or other alkaline metal, free potassium being taken up by the mercury; thirdly, the introduction to the tank of the solution, and its treatment therein; and fourthly, the recovery of the solvent by regeneration. In the first stage, although it is not so described, Molloy must subject the pulverized ore to a process of leaching to obtain his solution, say Au Cn.

The following equation expresses it :

$$HO + O + 4KCN = 2Au2\,[KAu\,(C\,N)_2] + 2KHO.$$

In the second stage, his alkali metal is an alkali salt, i. e., potassium carbonate ($K_2\,CO_3$) or a sodium carbonate, etc. No reference is made to the anode used in electrolytically charging the cathode, but the object to be attained is apparently that the mercury in the cathode should take up free potassium, forming an amalgam of these. This addition may be made mechanically as an alternative.

In the third stage, which is that in which the extraction of the precious metals takes place, the solution comes in contact with the previously prepared mercury. It is said that it "rests or passes over" it; so it is not an "agitation," though it may be called a "circulation" process.

Although it is not easy to gather from the inventor's description that he uses electricity in this stage it is evidently implied, because the reactions in the following equations could not otherwise be effected:

$$2\,[K\,Au\,(CN)_2] + H_2 = 2\,KCN + 2\,HCN + 2\,Au;$$
$$2\,CNH + 2\,KOH = 2\,KCN + 2\,H_2O.$$

In the first equation we have the action of the nascent hydrogen on the double cyanide of gold and potassium cyanide, producing metallic gold and hydrocyanic acid. The gold is precipitated and absorbed by the mercury, from which it is afterwards released in the usual way.

In the second equation we find that the hydrocyanic acid unites with caustic potash formed from the alkaline metal in the mercury, and re-forms potassium cyanide, which is one of the important features of the invention. The recovery of the cyanide will constitute the fourth stage.

The entire absence in the specification of the position of the other electrode, and the description of his apparatus being confined to merely the words "many forms of construction," seem to exclude claims to originality in that respect; there being no attempt to describe something that the ordinary engineering mind can construct or put to work.

In January, 1893, E. D. Kendall applied for, and in August, 1894, was granted a patent in the United States for a method which claims to be "a method" of treating pulverized gold and silver ores with sodium dioxide and a "suitable cyanide" in a water solution. The quantities of chemicals to the ton of ore are 2 lbs. of sodium dioxide ($Na_2\,O_2$) and 7 lbs. of potassium cyanide (KCN), but these may vary. The treatment may be by lixiviation, "with or without" agitation. And the precious metals may be separated from the lixivium by "electrolysis or other suitable means." No apparatus or special means are described.

Also, in December, 1893, Carl Pielsticker obtained a patent in New Zealand for the extraction of gold and silver from ores, both in the form of sulphide, and in ores in which the precious metals exist in a state of "extremely fine division."

The use of this process was chiefly the cause of the well-known litigation between the Cassel Gold Extracting Company, the owners of the MacArthur-Forrest process, and the Cyanide Gold Recovery Syndicate, by which an attempt to monopolize the use of potassium cyanide in all processes of gold extraction throughout the world, broke down. It is for this reason, and as helping to explain the difference between "agitation" and "circulation" in a cyanide solution, that my notes include its description.

Its essential features may be briefly described as "a process of separating gold and silver from their ores," which consists in treating the powdered ores with a solution of cyanide of potassium, in conjunction with an electric current of low tension used for the purpose of the deposition of the precious metals. In order that the process may go on continuously, he produces a circulation of the liquid through the space between electrodes, which are fixed respectively, the anode at the bottom and the cathode at the top of a tank.

It is claimed for the use of a current of higher potential specified to be used in the ore tank that "the precious metals are attacked more energetically by a cyanide solution in connection with a current of electricity than without." We are told that "free gold is certainly more quickly dissolved by cyanide of potassium in conjunction with an electrical current than without one."

To recapitulate : This process has, in common with Rae and his successors, the combination of a solution of potassium cyanide with an electric current, by which it assists solution and effects precipitation on a cathode; and in common with Molloy, it effects the treatment in more than one stage, and by means of "circulation." In this latter respect Molloy and Pielsticker are at one with the process of Siemens & Halske, in contradistinction to the processes in which "agitation" is essential. With reference to my observations further on as to "agitation," it may be here observed that in such processes the density of the sludge at various points in the system of circulation must depend on its rate of motion.

Edwards, in April, 1894, described, in the United States, an apparatus very similar to Hannay's, except that the position of the carbon anodes is altered, and they are apparently placed so as to line the sides of the treatment vessel.

It 1894 an invention was produced in the United States, and subsequently patented there and in other countries by Messrs. Pelatan and Clerici, for an electrolytic process and apparatus for extracting gold and silver from their ores and other compounds.

The process has been described as a single continuous one—an essential feature—because as such it has proved itself equal to effect in one operation all that can be expected of it. In other words, it receives the pulverized ore in a wet condition, and after being stirred up, and water if necessary added, so as to be in a condition of fluidity to allow of suitable agitation of the particular kind of ore under treatment, and so that the chemicals used in the treatment are properly mixed with the solution, it is introduced into the treatment vat or vats, in which the operation, which I shall again refer to, is carried out until nearly all the precious metals are extracted and absorbed by the amalgam at the bottom of the vessel or vessels. Although a preliminary mixing of the solution in a separate tank may be thus implied, there is nothing to prevent the mixing being carried out in the treatment tank itself.

In this we have, I believe, for the first time, a process and apparatus which effectively combines, in a way that can be constructed and worked by a workman of average intelligence, the following :

(1) A vat made of a material, dielectric in its nature; (2) an agitating apparatus of various specific forms, each form calculated to carry out one and the same process—being the result of considerable experience—having an agitator, part of which constitutes the anode in an electrolytic circuit, which is carried so that it can by no means make contact with the bottom or sides of the vat; (3) the presence of a cathode, which covers the whole of the bottom of the vat, made of a metal (preferably copper) plate or sheet, and suitably contained and fixed so as to carry on it a layer of mercury; (4) the use of a graduated current from an electrical generator, having large quantity and low potential; (5) the mixture or sludge under treatment being composed of water in given proportions, ore finely pulverized, potassium cyanide or other solvent of gold and silver, and common salt, with the addition as required during the process of alkalis or organic acids as may be required.

These are the chief features, together with important details of construction to which I shall refer further on, that constitute the Pelatan-Clerici process.

(*To be continued.*)

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

THE OVERHEAD LINE AND GROUND RETURN CIRCUIT OF ELECTRIC STREET RAILWAYS.*

BY DAVID PEPPER, JR.,
Member of the Institute.

On the proper design and careful construction of the line and ground return circuit depends, to a great extent, the satisfactory and economical operation of an electric railway. The practice of the present time is the result of costly experience. Within the last few years there have been great advances made in the character of the outside work, and the materials entering into the construction have been greatly improved. In the early days of electric street railways, the importance of the line, and especially the return circuit, was very little thought of. The cheapest form of construction that would cause the cars to move at all was usually installed. Managers now find that it is very bad economy to attempt to save money on their outside work. The direct loss in receipts and prestige, owing to failure of the outside construction, is very great, and the loss in power, owing to poorly proportioned or poorly constructed work, is a constant loss. The overhead trolley line should have sufficient strength in all its parts not only to hold up the dead weight of the trolley wire, but to resist all sudden and heavy strains caused by blows from trolley poles, the falling of outside wires upon the trolley wire, and the breaking of the trolley wire.

The trolley wire in city work is usually supported on iron poles placed, about 125 feet apart, in pairs on opposite sides of the street. These poles are usually made of from two to three sections of heavy iron pipe, telescoped into each other about 18 inches and the joints swedged while hot. On straight line construction, unless the street is very wide, poles 28 feet long and weighing from 700 to 750 pounds are used. On wide streets and light curves, and with extra heavy trolley wire, poles from 900 to 1,100 pounds are used. On heavy curves the poles weigh 1,300 pounds and over. In setting these poles great care must be taken that they are set in such a way that there is no give at the base of the poles. If the poles give after the strain is put on them, it will loosen up the entire line, especially at curves and special work, and cause a great deal of trouble in repairing. The lighter weight poles, when set in fairly good ground and with a curbstone in front, should be placed in holes from 18 to 20 inches in diameter and from 6 to 6½ feet deep, and set with a rake to allow for straightening when strain is placed on them. The concrete used should be made of 1½ bags of improved natural cement, one barrel of sand and sufficient stone to fill the hole. The sand and cement should be made into a thin mortar, mixed with the wetted stone, turned at least three times, and the mixture then rammed in the hole in six-inch layers. The concrete will be worthless if it is not properly rammed or if there is too much or too little water in it. For pull-off poles, and where there are heavy strains, two bags of cement should be used and the poles set in larger and deeper holes.

In cross suspension work the span wires are usually secured to poles with wrought iron bands and one or two mechanical insulators are placed in each end of span near pole. In the early construction silicon bronze and solid steel and iron wires were used for the spans. It was found that the tensile strength of these wires, if they were scratched or kinked in any way, was greatly reduced and that there composition was somewhat uncertain. Seven-strand galvanized steel cable is now used, $\frac{5}{16}$ of an inch in diameter for ordinary single-track suspension and pull-offs, and $\frac{7}{16}$ of an inch on long spans and ⅜ trolley construction.

Care should be taken in placing spans to allow for the proper sag when the suspension device is sprung on the span wire. If the span is tight, say having a sag of only 8 inches in 35 or 40 feet, there is great strain put on the pole. If the sag is too great, the line will look bad and violent vibrations will be set up in it every time a car passes. The exact tension of the spans is a matter of skill on the part of the man putting them up.

The insulators used in the span wire are of many types and makes. The insulation is usually hard-rubber compound or one of the many special compounds made for this purpose. There is a heavy strain sometimes placed on these span wires, and the constant vibration will quickly find any imperfections in the insulating material and cause either a break in the wire or a leak to the pole. Those forms of insulators involving screw connections are not usually as strong as those of rigid type, and, as the take-up is seldom if ever used in practice, it is better economy to use two solid strain insulators instead of a turnbuckle.

In many cases where the track is on the side of the street, a single line of poles is used and the trolley wire suspended from a pipe bracket, which is usually trussed in some manner. A plain bracket gives a rigid line which causes a great deal of wear and tear. To overcome this rigidity brackets are often made so as to rise a little under the pressure of the trolley, or the hanger is secured to a span wire under the bracket. Bracket construction, unless securely guyed, is much more liable to serious damage than span construction, owing to the lack of strength laterally if the wire breaks or if the trolley pole comes off and strikes the bracket.

We now come to the method of actually suspending the trolley wire. There is sprung on the span wire a casting of malleable iron or bronze, containing an insulated bolt of from ⅜ to ¾ of an inch in diameter. This insulated bolt is sometimes placed in the casting and the top screwed down. In others it is contained in the body of the insulating material within the bell. The latter form is probably the best, owing to the much better protection given the insulating material from blows from the trolley wheel and from the weather. The principal advantage claimed for the other form of insulated bolt is that only one portion has to be thrown away in case of failure to work properly.

At curves, the trolley wire is suspended by special pull-off hangers placed sufficiently close to prevent sharp bends in the trolley wire. The usual distance is from 6 to 10 feet, depending, of course, upon the degree of curvature. Where pull-off wires cross the straight line trolley wire, they should be secured to it the same as at the spans. The pull-off wires should all come together in an extra heavy strain insulator at the pull-off pole. It is well at this point to have a turnbuckle capable of tightening the entire series of pull-offs. Care should be taken in all pull-offs and special work to have each and every pull-off wire insulated from its neighbor in such a way that in case of a failure of the pull-off insulation from the trolley to the pull-off wire only one wire will be alive. When this precaution is not taken, it causes a great deal of trouble in locating the leak in a complicated curve.

In iron pole construction the insulation is an important item, first, to prevent leakage to the trolley pole, which not only causes a steady loss but, perhaps, the shutting down of the lines, and also as a matter of safety to the men working on the live trolley wire. It is very disconcerting to a lineman working on a ladder or tower wagon to unexpectedly discover that the span wire, which he thought was insulated, is connected directly to the ground through the pole.

Probably one of the most important matters in trolley construction is the method of suspending the trolley wire from the hangers, and this is especially true on roads where the cars run at a speed exceeding ten miles an hour. The slightest obstruction on the underside of the trolley wire will cause the trolley wheel to leave the wire a short distance to come back again with a sharp blow. Each time the wheel leaves the wire there is an arc formed that takes off a small portion of the wheel or wire. If the obstruction is sufficient the wheel will be thrown so far down from the wire that on its return it will miss the wire and go down the line, striking span wires and special work and straining every part of the overhead construction. This is one of the principal causes of trouble on the line. Probably one of the most satisfactory methods of suspending the wire is by using a bronze or composition ear, 15 inches long, with a groove of the diameter of the wire, milled in the solid of the lower portion of the ear, the depth of this groove to be about the diameter of the wire. The extra portion of the metal is so proportioned that it can be securely hammered down on the trolley wire. The ear should then be carefully soldered, using soldering salts and solder; this, when properly done, makes a first-class job, but there is danger that the wire may be damaged by careless or unskilled workmen. Should the iron be so hot as to partially anneal the trolley wire, there is a very great reduction in tensile strength at the ear, and the wire may be so damaged that on the first strain it will draw out and break. Only the most skilful men should be entrusted with this work, as it requires care and skill that can only be attained by practice.

To give a smooth under-running surface to the trolley wire many devices have been tried. The trolley wire has been rolled in the form of the figure 8 and a mechanical clamp devised to hold the wire in place, giving, theoretically, a smooth under-running surface. Unfortunately the wire in practice is likely to be twisted slightly in the erection and at curves, with the result that the trolley wheel runs on the two loops of the wire, giving extremely unsatisfactory results. To overcome this trouble the section of wire was modified to three points instead of two, and this has been found to work much better. Another plan, of good promise for high speed work, was to take a four naught round trolley wire and with a special machine to press or mill a groove on each side of the wire just above the diameter to fit a clamp. This device answers very well, but it is somewhat difficult to repair work put up in this manner. Another class of suspension involves the use of metal below the trolley wire. Others involve the kinking of the trolley wire. Both of these last-named methods are open to serious objections for high-speed roads.

Another important part in the work is the joining of the trolley wire. This can probably be best accomplished by a long, hard-rolled copper sleeve, about 18 inches long, turned to a cone at each end and so arranged by boring and milling grooves that the wires come out together in the middle of the sleeve. The hole is then soldered and the surplus wire cut off. Another style, without solder, involves some form of clamping device within the tube, the inner chamber being larger than the bore for the trolley wire to enter.

In all special work, such as frogs, cross-overs and section breaks, care should be taken to choose that which gives a clear under-running surface. In high-speed work the tendency is to entirely avoid switches and to substitute for same two trolley wires or cause the trolley to be lowered and placed on another wire on cars leaving the main line. At any speed above ten miles an hour, the chances are greatly in favor of the trolley wheel leaving the wire.

In the early days No. 6 to No. 4 B. & S. gauge wire was considered quite heavy enough for the trolley wire. It was soon discovered, however, that this was entirely too light, and for many years single naught hard-drawn copper wire was used. The tendency is strongly in favor, for standard city work, of the use of double naught wire. It has been proved by experience that the troubles from the

* Read before the Franklin Institute, 1898.

breaking of the trolley wires are reduced to about one-third the number when double naught wire is used. If single naught trolley wire is drawn so tightly that the up and down vibrations only show for three or four poles, the wire is strained well up towards its safety limit and will not stand a sudden and violent blow. The wire should be stretched so that in winter there will be a sag of about 10 inches in every 125 feet. This will make a considerably looser line in summer time.

In deciding upon the size of trolley wire there are several other problems to be considered besides the tensile strength and freedom from accidents. In a network of wires such as here in Philadelphia, the trolley wire is not usually depended upon as part of the feeder system, other than for six or eight cars on a single section. In suburban lines, with comparatively few cars, the question of using the trolley wire as part of the feeder system becomes an important one; and the difference between one naught and two naught trolley, and still more so between two naught and four naught trolley, will determine whether or not a heavy feeder will have to be run alongside of the trolley wire. The cost of bare copper in the form of two naught or four naught trolley is considerably less per circular mil than the cost of a single naught trolley wire plus the necessary insulated feeder wire.

In designing any feeder system the proposed conditions upon which the line is to be run should be very well known, and the line designed for economy of current and original investment for average load, with the provision made that on very heavy loads the voltage will not fall below 375 volts for a few moments. One of the causes of the failure of insulation on iron-pole construction is the effect of lightning discharges on the line, which greatly weaken and strain the insulators, even if they do not break down on the first discharge. To overcome this it is usual to place one of the well-known and tried makes of lightning arrester at each feeder tap, providing it with a kicking coil, and being careful that there be as few bends as possible in the wire to the ground. The lightning arrester should preferably have a single naught tinned wire run down inside of the pole and connected securely to the return circuit and track. The mere grounding of a lightning arrester to a trolley pole set in concrete is not sufficient, as, even on a wet day, there have been cases known where the concrete acted as such a good insulator that there was a difference of potential of 475 volts from pole to track. On wooden-pole construction the problem of insulating is very much simplified, as 18 or 20 feet of wooden pole, properly painted, is probably as good an insulator as can be made. Wooden poles of sufficient weight and of first-class yellow pine, chestnut, oak or cedar, painted with a preservative compound at the butt and painted two coats of good paint, are as satisfactory as iron poles, and in the long run as well as in first cost are a little cheaper. They will last about one-third as long as the estimated life of an average iron pole properly painted.

The limitations to the overhead trolley are now quite generally recognized. It has been found that it is difficult to efficiently transmit by means of the ordinary form of trolley wheel more than 150 amperes from the wire to the wheel without excessive sparking and loss. The speed at which a trolley wheel will stay on the wire, through section insulators, special work and switches, is limited in good practice to not much over ten miles an hour. When the trolley stand and wheel are both designed for high speed and the line carefully constructed it is possible to run on straight-line work at a speed of about thirty miles an hour. Beyond this speed the tendency to throw the wheel from the wire, owing to slight obstructions on the trolley wire, is very great. If the wheel leaves the wire at this speed it is almost certain to either break the trolley pole or bring down a large portion of the overhead construction. It is for this reason that experiments have and are being tried to substitute a fixed conductor near the ground with a large surface contact for the overhead trolley wire for high speed and heavy currents.

A great deal of attention has recently been given to the matter of ground return. It has been found that the current on an imperfectly bonded track is likely to come back to the station through water and gas pipes and on the lead covering of underground cables, setting up electrolytic action, which, in some instances, speedily destroyed the pipes. In bonding a track, the first thing to be considered is to get as low a resistance as possible at each joint. It is also necessary to have an assurance that the bond will remain in perfect condition for a long period of time and will stand the maximum current that will be called upon to go through a special piece of track. The actual cost of the material for bonding a track, with most modern systems of bonding, is a small item compared to the original labor of putting it in place and the cost of re-bonding the track within a few years, without taking into consideration the watts daily lost in the bond circuit. Few persons realize how low a resistance a pair of nine-inch girder rails have, and that every effort should be made to get the full benefit of this return circuit. The resistance of the rail is from six to seven times the resistance of the same section of commercial copper. Very few tracks are bonded more than one-fourth or one-third the carrying capacity of the rail. It has been proved in practice that the earth and fishplates are not to be depended on as part of the return circuit for heavy currents.

The Resistance of the Human Body.

Mr. Dubois, of Berne, presented a note to the Académie des Sciences on the duration of the variable period of current flow when a potential difference is applied to the human body. He used a condenser connected to a battery through the resistance to be compared, and then made the circuit for a very short period by the fall of a steel pencil against a mass of steel. In this way the circuit was broken before the steady state was reached, and by measuring the charge on the condenser one point of the curve of rising pressure could be obtained. From this and the fixed potential difference the period of variable flow of current can be obtained. From comparative experiments, the author concludes that the human body during the period of variable current presents a reactance much smaller than the ohmic resistance. In fact, its capacity partially annuls the resistance. The resistance, however, of the body during the period of variable current is constant. The resistance increases with the length of the parts of the body in circuit, and depends also on the surface of the electrodes. Finally, he concludes that the body acts as a condenser with a liquid dielectric, having a capacity equal to about 0.165 microfarad.

A New Electric Light Station for Cologne.

The Municipality of Cologne has decided to erect a second electric light station, and has voted a sum of $250,000 for that purpose. The present electric light station, which has been running since 1891, has a capacity of 1,600 kilowatts, a lamp connection equivalent to 33,500 50-watt lamps and 600 10-ampere arc lamps, and a motor connection of 427 HP.

Street Railway Men to Meet.

The American Street Railway Association will meet in Boston on September 6, 7, 8 and 9. The Street Railway Accountants' Association will meet in Boston at the same time.

LONDON NOTES.

[From our London Correspondent.]

The Waterloo & City Electric Railway.

This line (underground tunnel, third rail,) is now in full working. On the opening day, August 9, the line was well patronized by the public. The fares are 2d. single and 3d. return. There are no intermediate stations. Each train consists of four coaches, open through, and carrying 240 passengers.

Isle of Man Electric Trams.

There has just been opened a further 10½ miles of electric trolley system in the Isle of Man. The Douglas & Laxey, Laxey & Snaefell and other lines have been so successful that this new line (Laxey to Ramsey) was proceeded with. It opens up a part of the island which has been practically inaccessible to tourists so far.

The Zipernowski & Deri Patents.

The first action to be taken against users of alternating current plant will be prosecuted against the London Electric Supply Corporation. It will be a test case, and if successful Mr. Martin Rucker and the syndicate which has purchased the Zipernowsky & Deri transformer patent rights of 1885 for the remainder of the term will proceed against all municipalities and companies infringing the patents. The Municipal Electrical Association has met in London and resolved to contest the claims to the extremity of going to the House of Lords on appeal if they are defeated in the lower courts. The general opinion is that the courts will not be likely to grant damages or royalties after the patents have been infringed without objection on the part of the patentees for the past ten years. It is hoped in some quarters that the bold front which alternating station owners are putting on will convince Mr. Rucker that his game may not be worth the playing. However, the circulation of his legal letters among the municipalities interested is giving rise to some apprehension, and a few holders of shares in some of the London supply companies display nervousness and are disposing of their holdings.

Multiphase Plant for Manchester.

The Manchester Corporation has a very extensive scheme in hand for supplying the surrounding districts with lighting current from its main generating works. In connection with this scheme the Corporation has just placed a large order for three-phase machinery with Thomas Richardson & Sons of Hartlepool and Brown, Boveri & Co. of Baden. The order comprises rotary converters of an aggregate capacity of 1,200 units with three-phase static transformers of the same type, and also the necessary high and low tension switchboards for the control and regulation of the above. Continuous current will be taken from the omnibus bars of the central station switchboard and transformed by means of the rotary and static transformers to three-phase current at a tension of 5,000 volts. This will be distributed by means of high tension triple conductor cables from the main station at Dickinson street, Manchester, to the different sub-stations, where it will again be converted into continuous current and be distributed to the consumers on the three-wire system with 400 volts between the outers.

CANADIAN NOTES.

The directors of the Bell Telephone Company (Canada) have decided to increase the capital of the company from $3,168,000 to $3,900,000.

Tenders are invited up to August 30 for supplying an incandescent electric lighting plant for the city of Beeton, Ont. Mr. John Galt, C. E. and M. E., is the consulting engineer, and Mr. W. H. Mitchell is the chairman of the electric light committee.

BOOK REVIEWS.

HOW TWO BOYS MADE THEIR OWN ELECTRICAL APPARATUS. By THOMAS M. ST. JOHN, M. E. 140 pages. Price, in cloth, $1.00.

Those who visited the Electrical Exhibition last May cannot have failed to notice on the south gallery a very interesting exhibit, consisting as it did of electrical apparatus made by boys. The various devices there shown, comprising electro-magnets, telegraph keys and sounders, resistance coils, etc., were turned out by boys following the instructions given in the book with the above title, which is unquestionably one of the most practical little works yet written that treat of similar subjects, for with but a limited amount of mechanical knowledge and by closely following the instructions given, almost any electrical device may be made at very small expense. That such a book fills a long felt want may be inferred from the number of inquiries we are constantly receiving from persons desiring to make their own induction coils and other apparatus.

LIGHTING BY ACETYLENE. By WILLIAM E. GIBBS, M.E. 141 pages. Published by D. Van Nostrand Company, New York. Price, bound in cloth, $1.50.

In this work the author defends the use of acetylene gas, gives its history, points out the dangers attending its use, describes its method of manufacture as well as the various types of burners now on the market. The tables at the end of the book giving the United States patents on calcium carbide and acetylene apparatus are not only interesting but valuable. The pages devoted to the rules and regulations of the New York Board of Fire Underwriters regarding the use of acetylene should likewise be found of value. There are some seventy handsome illustrations of calcium carbide works, apparatus and electrical furnaces. The work is unquestionably a valuable one, carefully compiled and apparently dealing with its subject from an unbiased standpoint.

THE TELEPHONE. By WILLIAM J. HOPKINS. 83 pages, bound in cloth. Published by Longmans, Green & Co, New York, London and Bombay.

This little work, as the author states in the preface, explains in detail the principles underlying the action and the design of telephone transmitters and receivers. The book is divided into eight chapters, the first of which explains the action of sound and shows the curves traced by sounding bodies. The second chapter deals with the history of the telephone and is very interesting. Chapter III describes various transmitters and treats of their development, as does Chapters IV, V and VI. Chapter VII treats of magneto instruments. The last chapter is devoted to the discussion of the proper design of receivers. Altogether this little work contains an immense amount of useful information without burdening one with a description of every good, bad and indifferent telephone instrument now on the market.

LEGAL NOTES.

Judge Lacombe in the United States Circuit Court, New York, has granted to the Thomson-Houston Electric Company a preliminary injunction against the Union Railway Company, which is accused of infringing electrical patents. The court found that the company had infringed the 3d, 4th, 14th, 19th, 20th, 23d, 25th, 26th and 27th specifications of U. S. letters patent No. 424,695, said to be owned by the Thomson-Houston Company. The infringing apparatus was furnished by the Walker Company.

Two suits in foreign attachments, aggregating over $26,000, were brought in the Protbonotary's office at Allentown, Pa., on the 11th inst. against the John Stephenson Company of New York, manufacturers of trolley cars. The plaintiffs are William P. Young's Bros., whose claim is $10,372.33, and the Sprague Electric Company of New Jersey, which sues for $16,108.40.

At Pottsville, Pa., on the 17th inst., Judge G. A. Endlich confirmed in a lengthy opinion the verdict of $10,000 damages which a jury last January found against the Schuylkill Electric Railway Company in favor of Elmer J. Walbridge, aged 6 years, who had both hands taken off at the wrist by being run over two years ago on the railway. It is said the car was being run by but one man at the time.

Three applications for receiver for the Citizens' Electric Light & Power Company of Kokomo, Ind., were filed on the 12th inst., with claims aggregating $12,800, by the American Savings Bank of Grand Rapids, Mich., the Capital City National Bank and Joseph L. Cohn of Indianapolis. The corporation is capitalized at $40,000.

The Thomson-Houston Electric Company of Connecticut has filed suit, alleging infringement on patented alternating current motor devices, against the Dayton Fan & Motor Company, Dayton, O., and E. O. Waymire. They ask for an injunction and damages.

THE NEWS.

What is Going On in the Electrical World.

STREET RAILWAYS.

Amherst, Mass.—The directors of the Amherst Street Railway Company are seriously considering the advisability of building an extension from Amherst to South Hadley, which would insure a direct connection between Holyoke and Amherst.

Aurora, Ill.—The projectors of the Aurora, Yorkville & Morris Electric Railway now have matters so well in hand that it is expected work on the line will soon begin. The necessary arrangements are about consummated and the officials think that the first week in September will see construction work started.

Belding, Mich.—A number of Grand Rapids capitalists have organized a company, to be known as the Grand Rapids & Belding Traction Company, for the purpose of building an electric road from Grand Rapids to this city. J. W. Trufant, of Mt. Clemens, has asked the city council for a franchise for an electric road also running from Grand Rapids to Belding. This is a distinct line. Mr. Trufant is backed by prominent Detroit capitalists.

Clayville, N. Y.—At a meeting held here to discuss the subject of an electric railway for the town, 95 per cent. of those present favored the project, and efforts are to be made to secure the building of a road connecting Clayville with Utica.

Defiance, O.—Receiver Faben of the Defiance Light & Railway Company has been authorized by Judge Hubbard to sell the railway property owned by the company. The receiver, it is said, has had an offer from parties who are prepared to buy the road and place it in operation.

Detroit, Mich.—A new suburban railway company has been organized here called the Detroit, Utica & Romeo Railway Company, with $300,000 capital, half paid in, mainly through the efforts of George B. Davis, ex-member of the Legislature from Macomb county. The directors are A. McVittie, Frank E. Kirby, Frank B. Andrus and Elliott G. Stevenson, of Detroit; George B. Davis of Utica, and M. I. Brabb, of Romeo. Bonuses aggregating $45,000 have been subscribed as follows: North Detroit and Romeo, $15,000 each; Utica and Warren, $5,000 each, and Disco and Washington jointly, $5,000. Most of the franchises and right of way have been secured. It is hoped to have cars running by January 1. The motive power will be either electricity or compressed steam.

Durand, Mich.—The village council has granted a franchise to the Long Lake, Durand & Corunna Electric Street Railway Company. By the terms of the franchise the company is to be organized and the work commenced within three months from the date of the franchise, and the road in operation by January 1, 1900. It will run from Corunna through Durand to Long Lake, and from there on to Detroit. Wm. E. Avery of Detroit is at the head of the company.

East Windsor, Conn.—At a meeting of the incorporators of the East Windsor Railway Company to discuss the proposition of George W. Dunham of New York, who has secured the charter of the Springfield & Southwestern Railroad, it was decided to dispose of their charter to Mr. Dunham for a sum that will cover the expense of securing it, etc., on the condition that he will give a written guarantee that he will build the road within a given time.

Elmira, N. Y.—The "Telegram" says: "Parties interested in the Elmira & Seneca Lake Railway Company, which proposes one of these days to lay an electric road from Horseheads to Watkins have been looking over the ground recently and there are rumors in circulation that there is a prospect of the company's soon floating its bonds, in which event it is supposed that work on the road would soon be commenced."

Hudson, N. Y.—The Hudson City Street Railway has been sold to the Brooklyn Traction Company, which has also secured control of the Kinderhook & Hudson steam railroad. The latter will be converted into a trolley road to run in connection with the Hudson City, which is to be extended to Philmont, and it is said the road will in time run to Nassau, thence to Albany, and finally connect with Troy and Cohoes. The consideration for the franchises and property is placed at $500,000.

Kansas City, Mo.—The "Journal" states that the Jackson County Railway Company, which will be incorporated at once with a capitalization of $100,000, with F. W. Sears as the president, a few days ago made application in the county court for franchises for two lines of electric railway, one to follow Independence avenue from the eastern limits of the city and the other from the southern city limits to Dodson. It is understood that those associated with Mr. Sears are Kansas City men, and that the purpose of the company is to establish cheap fare roads to the suburbs of the city with which they will connect.

Lawrence, Kan.—T. A. Allen, the engineer in the employ of the promoters of the electric railway, is at work on maps showing the routes that will be feasible for the new road to use. The plans for the power house have been completed and are in the hands of the men who will build the road.

Milwaukee, Wis.—General Manager Beggs of the Milwaukee Railway Company says the long-talked of Milwaukee and Chicago electric railway line needs only the building of the connecting link between Kenosha and Waukegan to complete it. This line will soon be built.

New York.—The Metropolitan Street Railway Company is said to be contemplating an extension of its electric railway system to Seventh avenue from the northern end of Central Park to the Harlem River.

Portland, Ind.—The contract for an electric railway between Redkey and Dunkirk has been awarded to the Electrical Installation Company of New York and Chicago, and work is to be commenced at once. The line will probably be extended to Pennville.

San Francisco.—Ground has been broken here for what will probably be the shortest electric railway in the world. The road is to be only half a mile in length and will run on San Bruno avenue from the San Jose road to Mount Olivet cemetery. Only one car will be used, and a transfer arrangement has been made with the San Mateo Railway. The directors of the new road are also the directors of the Mount Olivet Cemetery Association.

Wichita, Kan.—The city council has extended the franchise given to W. Q. Church of New York for a street railway in this city. The time of the original franchise granted to Mr. Church expired some time ago, and he had some difficulty in getting an extension, but finally succeeded. He has deposited $10,000 in the city treasury as a guarantee that the road will be completed by March, 1899.

LIGHTING PLANTS.

Arlington, Ga.—The city council has under consideration a petition for an election to determine the question of issuing bonds for the establishment of waterworks and an electric light plant.

Brooklyn, N. Y.—Deputy Commissioner Walton of the Department of Public Buildings, Lighting & Supplies is completing arrangements to have a meter and light testing bureau in Brooklyn. The charter provides that all meters be regularly tested and also the gas and electric light furnished the city, so that the proper candle power may be insured.

Cleveland, O.—The Consumers' Electric Company is the name chosen by the promoters for the proposed organization which is intended to enter into competition with the Cleveland Electric Illuminating Company on the West Side. The nominal capitalization of the company is $30,000, and the officers of the preliminary organization are A. W. Oppman, president and treasurer; John Meckes, vice-president, and Charles P. Salen, secretary.

Lansdowne, Pa.—Application has been made for a charter for the Lansdowne Electric Light Co. which purposes to furnish light, heat and power to this borough and vicinity. The incorporators are Tamany P. Street, Henry C. Staatzel, Richardson Shoemaker, J. Milton Lutz and Murtha J. Kelly.

Mansfield, Pa.—The Mansfield Electric Company has submitted to the council a proposition to light the streets of the borough with 16 CP. incandescent lights at $10 per lamp a year.

Medway, Mass.—The new electric light company has organized with John McGuinnes president, Clark P. Harding secretary, and the following directors: Charles H. Dean, John D. Shipper, George Harding and Daniel S. Woodman. The company will light the streets of the town beginning September 15.

Orangeburg, S. C.—A meeting will be held here at an early date to discuss the questions of waterworks and electric lights.

San Bernardino, Cal.—B. C. Roos, the former manager f the electric plant, has had plans prepared for an

electric and gas plant which he proposes to establish on a basis that will make lights one-third the present rate. The motive power for generating the electricity is to be steam.

South Amboy, N. J.—J. A. Carr of Hackettstown has made application to the borough council for a franchise to operate an electric light and heating plant in South Amboy, and an ordinance has been framed for the action of the council at its next meeting.

Tallahassee, Fla.—There is talk here of putting in an electric light plant at the expense of the taxpayers. A citizen has been getting estimates for a plant with a capacity for 100 arc and 3,000 incandescent lights and the outside figures were $12,000.

Watertown, S. D.—O. M. Kirlin and others have been granted a franchise for the erection of an electric light plant in Watertown. The plant will be entirely new and up to date.

MANUFACTURING, ETC.

Dixon, Ill.—The Dixon Power & Lighting Company are putting in two Leffel turbine wheels at their recently purchased property on the river. The turbines are guaranteed 114 HP. each with a six foot head of water. The company are making several improvements in their plant, including a new 240 HP. generator for arc and incandescent lighting, and will supply power for the shoe factories of Henderson & Co., and for other manufacturers.

Hartford, Conn.—An electric carriage built by the Pope Manufacturing Company was awarded the first prize for elegance at the special automobile meet recently held at Spa, Belgium.

Philadelphia.—Application will be made to the Governor of the State on September 5 by Albert G. Davids, Wilson Pierson, William J. Greer, Howard R. Penrose and George E. Scuse, under the Act of Assembly of the Commonwealth of Pennsylvania, entitled "An Act to provide for the incorporation and regulation of motor power companies for operating passenger railways by cable, electrical or other means," approved March 22, 1887, for the charter of an intended corporation, to be called the Southwestern Traction Company of Philadelphia, the character and object of which is the construction and operation of motors and cables or other machinery for supplying motive power to passenger railways and the necessary apparatus for supplying the same.

Pittsburg, Pa.—The "Times" of the 15th inst. states that the Westinghouse Electric & Manufacturing Company has just concluded the contract for the installation of the complete electric equipment for the Snowqualmie Falls Power Company's big plant at Snowqualmie Falls, Wash. The first installation will be for 10,000 horse power and 20,000 horse power will soon be added. The president and principal owner of the Snowqualmie Company is William T. Baker, of Chicago, who was the first president of the World's Fair Commission.

San Francisco.—The Fort Wayne Electric Corporation and the Tuthill Water Wheel Company have shipped by vessel from this port the first electric lighting and power apparatus ever sent from this city to South America. It is for the Yanni Development Company, which is controlled by the Rothschild syndicate in London. Up to this time all mining equipment has been sent there from London and Germany. The machinery will be landed in Peru and sent overland 600 miles to the mines in the Andes beyond Lake Titicaca in Bolivia.

Washington, D. C.—The Navy Department is inviting sealed proposals until August 30 for two pairs of runways, erected on foundations in building No. 20, Brooklyn Navy Yard, together with lateral bracing and two electric traveling cranes of 20,000 pounds lifting capacity, with three motors each, for lifting and traversing the same with loads. The crane will be operated by means of electricity, having an independent motor for each motion, hoisting, traverse and longitudinal traverse, operated from the floor and receiving the current from wire and trolley arranged at the ends. Intending bidders desiring specifications, blank forms of proposals and other information can obtain the same upon application to the Navy Pay Office at New York, or to the Bureau of Supplies and Accounts, Navy Department, Washington, D. C.

TRANSMISSION PLANTS.

Colorado Springs, Col.—At noon on the 17th inst. Governor Adams turned on the electricity by which hereafter the gold mines of Cripple Creek will be run and lighted. Steam will be entirely replaced in all the leading mines by electricity generated at Canon City, twenty-four miles south of the camp. The first mines in the district to receive the benefit of this potent power will be the Trilby, operated under lease by Tabor & Ferguson, the workings of the old Bird & Gill lease on the Wisconsin, and the Dustline & Miller lease on the same property. At these mines electric hoists have been put in, while other properties are still awaiting the arrival of the electric equipment, delayed in the Eastern factories through demands due to the war.

Dumont, Col.—The electrical power plant that is under way for this place will somewhat revolutionize power in this camp. The tunnels, mills and mines are to be supplied with electric power, and drills will be operated by electricity instead of air. It is the intention also to put in steam power, to be used during the low stages of the creek. The company is organized in Ohio and has at its head some of the wealthiest men of Cleveland. One of their number has been here examining the outlook and he is highly gratified with the showing. Water rights have been secured along Clear Creek for two miles, in addition to the acquiring of ground near Empire for the storage of water.

Lockport, N. Y.—On the 10th inst., electric current generated at Niagara Falls was brought to this city by way of Tonawanda and lighted the Buffalo & Lockport Electric Railroad Company's power house here. The distance over the wires is about 30 miles.

Mechanicville, N. Y.—The immense plant of the Hudson River Power Transmission Company, which has been in process of building for more than a year, is now finished and power is being furnished therefrom. The dam of this company is, it is stated, one of the finest in the world. In length it measures about 2,000 feet; its central part rests upon a rocky island and it is 18 feet high. The dam is situated about two miles below the village of Mechanicville. It is built of concrete; at the end of the dam heavy piers of concrete of a circular plan are anchored securely to the shore. The plan, as prepared by the chief engineer, called for seven dynamos, but only five have been installed. These generators are of the General Electric three-phase type. Four turbines, each forty-two inches in diameter, are mounted on each shaft for the operation of a dynamo. Under the conditions of operation the wheels, which will work under a head of 18 feet of water, are expected to develop 250 horse power each. It is expected that power will be distributed to Albany, Troy and many other towns and cities near Mechanicville. The power house is a large brick building with heavy steel beams, an iron roof and concrete floor. The first floor is devoted entirely to the dynamos and their appurtenances, while the second floor, which is on a level with the dam, is given up to offices. The dam has caused the water to overflow nearly fifty acres on the east side. On the north side of the building a broad walk leads to Bluff Island, which supports the center of the dam. This new enterprise has attracted much attention and many visitors have been in attendance during its construction. The General Electric Company will use 2,000 of the 6,000 horse power of the plant. Several surrounding cities will undoubtedly make application for power in the near future.

Porterville, Cal.—W. H. Hammond has returned from England, where he went to obtain financial backing for a scheme to develop electrical power in Tulare county. He claims to have been successful and is making contracts to furnish power for irrigation and other purposes. The plant will be established twenty-nine miles east of Visalia on the Kaweah River. The cost of putting in the plant and extending the system to Visalia, Tulare, Porterville and Lindsay is estimated at about $250,000.

COMPANY MATTERS.

San Antonio, Tex.—John H. Clark of this city has been appointed receiver of the West End Street Railway Company. The appointment was made by the court upon the application of the bondholders.

New Haven, Conn.—The stockholders of the New Haven Street Railway have authorized the board of directors to purchase the New Haven & East Haven River Railway. The purchase will be provided for by a bond issue of $100,000 at 5 per cent. in the nature of a first mortgage on the new property. Bonds to cover a second mortgage will also be issued and a new issue of stock is also under consideration.

PERSONAL AND MISCELLANEA.

Several conductors of the Citizens' Street Railway in Detroit have been arrested for using bogus tickets on their cars and pocketing the proceeds of their sale to passengers. The Detroit detectives believe that the bogus tickets are manufactured in Chicago and circulated by an organized gang.

Electricity is being substituted for steam power in turning the city's bridges at Chicago. The new Fullerton avenue bridge is the latest to be thus equipped. During the season Rush, State, Dearborn, Clark, Wells, Lake, Randolph, Washington, Adams, Jackson and North Halsted street bridges have been equipped with new machinery at a cost varying from $600 to $1,000 each. The Van Buren street bridge has been operated by electricity since its construction. Power for the electric machinery is taken directly from the trolley wires of the street-car companies crossing the bridges, and only the amount used is paid for.

Thomas Nevins, a retired New Jersey street railway magnate, who went to Ireland on a visit two years ago and while there purchased Killeen Castle, returned to his former home in Orange last week for a four months' stay. While abroad Mr. Nevins secured a trolley franchise in Cheltenham, Eng., and a short time ago he purchased Mount Shannon Castle, the seat of the Earl of Clare. This is larger than Killeen Castle, and is situated in the county of Limerick, about three miles from the city of that name. The residence contains sixty apartments, and there are stables, farmyards, outoffices, stewards' and gardeners' houses, kitchen gardens and pleasure grounds. There are 1,000 acres in the place. The three coach houses on the place have stalls for thirty-five hunting horses, and the cattle house will accommodate 1,000 cattle. Five acres of the estate are walled in for tilling. A private gas works adjoins the house, and there is an abundant supply of water. The woods are filled with ancient growths of beech, oak, larch, sycamore and elm and stocked with plenty of game and wild fowl.

Henry L. Harris, a great-grandson of John Harris, the founder of Harrisburg, Pa., died at his home in that city on the 16th inst. He was for years an expert telegrapher, but was stricken with paralysis a few years ago. He was in his 61st year. He was manager of the Western Union Telegraph Company in Harrisburg for several years. During the Civil War he had charge of the telegraph lines between Baltimore and Washington, and also had headquarters at Gettysburg previous to and during the battle. Later he was sent to Philadelphia and was one of the first four operators employed in the Quaker City by the Western Union Company. He was the first operator to receive a message by sound in Harrisburg.

The superstition that human beings should sleep with their heads to the north is believed by the French to have for its foundation a scientific fact. They affirm that each human system is in itself an electric battery, the head being one of the electrodes, the feet the other. Their proof was discovered from experiments which the Academy of Science was allowed to make on the body of a man who was guillotined. This was taken the instant it fell and placed upon a pivot free to move as it might. The head part after a little vacillation, turned to the north, and the body then remained stationary. It was turned half-way round by one of the professors, and again the head end of the trunk moved slowly to the cardinal point due north, the same results being repeated until the final arrestation of organic movement.

RECENT COMPANY ELECTIONS.

Bangor & Oldtown Street Railway Company, Bangor, Me.—President and general manager, Elias Milliken; treasurer, John Cassidy of Bangor; clerk, A. J. Durgin of Orono.

Boston Electric Light Company, Boston, Mass.—President, F. A. Gilbert; vice-president, E. B. Maltby; clerk and treasurer, Samuel S. Silas; general manager, F. A. Gilbert; directors: the officers and Charles L. Lovering, Dexter N. Richards, William Butterfield, Charles Lowell, E. W. Burdett, William A. Paine; executive committee: F. A. Gilbert, Charles L. Lovering, Charles Lowell.

Brattleboro Street Railway Company, Brattleboro, Vt.—Directors: E. L. Waterman, H. L. Emerson, J. P. Sargent, S. S. Hunt, C. A. Smith. O. K. Jones was re-elected superintendent.

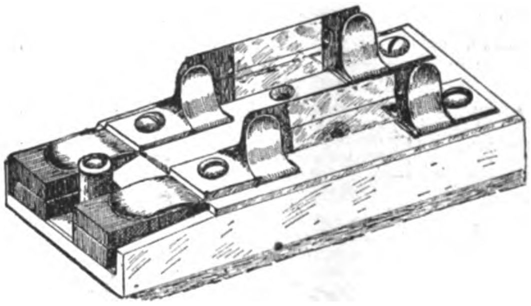
Toledo, Bowling Green & Fremont Electric Railroad Company, Toledo, O.—President, Edwin Jacoby, vice Frank J. Hoag resigned.

COMMERCIAL PARAGRAPHS.

A New Combined Fuse Block and Lightning Arrester.

The Telephone Department of the Electric Appliance Company, Chicago, has just placed upon the market a Combined Fuse Block and Lightning Arrester. It is an article of merit and will demand the attention of telephone exchange managers. It is $4\frac{1}{4}$ inches long by $1\frac{1}{4}$ inches wide. The illustration herewith gives a very fair idea of its appearance.

Absolute protection is secured from burn-outs from crosses caused by trolley and electric light lines breaking and falling across the telephone wires. It is a positive



lightning arrester and is practically indestructible. It requires no attention.

The effect of a lightning discharge across the carbon blocks is that of producing a small amount of carbon dust. This can easily be removed by pulling out the carbon blocks and blowing out the dust, then replacing them, and the arrester is in working order again.

The fuse end of the arrester should always be connected to the wires running to the instrument to be protected and the carbon arrester end directly to the line wires.

The lightning arrester, part of the block, is constructed with two carbon blocks, with perforated mica separating them. One block rests on the ground plate and the other is connected directly on the line, the idea being to produce an arrester on the air gap principle.

The perforations in the mica separator produce this result when the carbon blocks are placed in their proper position on the arrester.

The fuse portion of the arrester can be furnished with either the Postal or Western Union type terminals, an ordinary two-inch copper or foil terminal fuse being used. The base is made of porcelain.

INCORPORATIONS.

The Morrow Power & Electric Light Company, Morrow, O. Capital stock, $10,000.

The H. W. & M. Electric Company, New York. Capital stock, $25,000. Directors: Charles Hagedorn, Brooklyn, and two others.

The Perry Electric Light, Heat & Power Company, Newport, Pa. Capital stock, $18,000. Incorporators: A. D. Van Dyke and S. S. Leiby, Marysville; J. K. Van Dyke and John H. Smith, Philadelphia, and J. S. Leiby, Newport.

The Dunkirk & Redkey Traction Company, Dunkirk, Ind.—to build an electric railway connecting the two towns named in the title and others in Jay County. Capital stock, $75,000. Incorporators: H. C. Billingsly, Chas. A. Hanable, R. E. Hasbrouck, Elmer Bishop and W. H. Keyser.

The Rochester & Sodus Bay Railway Company, Rochester, N. Y.—to operate by electricity, compressed air or other power except steam, a railway line, 41 miles long, from Sodus Point to Rochester. Capital stock, $1,000,000. Directors: George E. Merchant, Walter B Duffy, Thomas J. Nicholl, Daniel G. Clapp, George Wilder, A. Master McDonnell, Joseph C. Gone, Ira M. Luddington, George Wilson, Charles Van Voorhis, Rochester; John A. Sullivan, New York.

The Keeseville Electric Company, Keeseville, Essex County, N. Y. Capital stock, $30,000. Directors: Orville S. Moore, H. M. Prime, A. W. Boynton, Keeseville; H. E. Barnard, Plattsburg; George F. Morse, Peru.

The Loveland Power & Electric Light Company, Loveland, O. Capital stock, $10,000. Incorporators: I. W. Newcomer, C. C. Stickelman, W. H. Stubbs, H. A. Coyne and R. B. Corwin.

ELECTRICAL PATENT RECORD.

Letters Patent Issued August 16, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

609,048. Motor-Car. Charles O. Palmer, Cleveland, O. Filed April 18, 1894. Renewed Jan. 25, 1898.
609,124. Electric Brake. Ernest B. Skinner, Ogden, Utah. Filed Oct. 30, 1897.
609,188. Electrical Traction. William Kingsland, Llandudno, England. Filed Dec. 23, 1897.
609,252. Electric Rail-Bond. Joseph S. Tucker, Chicago, Ill. Filed Jan. 20, 1897.
609,292. Switch and Switch-Operating Mechanism. James P. Orr and George H. Fugh, Pittsburg, Pa. Filed Nov. 9, 1897.
609,206. Car-Fender. Anton Mazzanovich, New York City. Filed Dec. 8, 1897.
609,394. Car-Fender. Timothy A. Remsen, New York City, assignor to Henry M. Lee, same place, and Mary E. Remsen. Filed Dec. 15, 1897.

ELECTRICAL MACHINERY AND APPARATUS.

609,092. Electric Controller. Joseph D. Forrer, Johnstown, Pa., assignor to the Steel Motor Company of Ohio. Filed July 11, 1898.
609,245. Electrical-Circuit Controller. Nikola Tesla, New York City. Filed Dec. 2, 1897.
609,246. Electric-Circuit Controller. Nikola Tesla, New York City. Filed Feb. 28, 1898. 609,247, 609,248 and 609,249, ditto. Filed March 12, 1898.
609,250. Electrical Igniter for Gas-Engines. Nikola Tesla, New York City. Filed Feb. 17, 1897. Renewed June 15, 1898.
609,251. Electric-Circuit Controller. Nikola Tesla, New York City. Filed June 3, 1897. Renewed June 15, 1898.
609,274. System of Control of Electric Motors. Edwin R. Gill, Englewood, N. J., assignor to the Invention Development Company of New Jersey. Filed April 4, 1898.

ELECTRIC ELEVATORS.

609,015. Electric Elevator. Rudolf Eickemeyer, Yonkers, N. Y. Filed Jan. 5, 1891.
609,016. Electric Elevator. Rudolf Eickemeyer, Yonkers, N. Y. Filed May 3, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

609,154. Electric Telegraphy. Oliver J. Lodge, Liverpool, England. Filed Feb. 1, 1898.
609,178. Telephone System. Alfred F. Swan, Bayonne, N. J. Filed Sept. 29, 1897.
609,229. Telephone System. Charles E. Egan, Burton L. Lawton and Ernest O. Wilcox, Meriden, Conn. Filed April 9, 1897.
609,331. Telephonic Measured-Service System. William W. Dean, Boston, Mass., assignor to the American Bell Telephone Company, same place. Filed Nov. 16, 1897.
609,374. Telephone Repeater or Relay. John S. Stone, Boston, Mass., assignor to the American Bell Telephone Company, same place. Filed Dec. 29, 1897.

BATTERIES.

609,142. Combined Battery and Electric Cell. Jules C. Dagoneau, Beaufort, France. Filed Jan. 15, 1895.
609,298. Primary Battery. Walter Rowbotham, London, England. Filed Feb. 24, 1898.

MISCELLANEOUS.

609,094. Method of and Apparatus for Making Electrical-Insulation Conduits. Hugo Gallinowski, St. Louis, Mo., assignor to the Lithosite Manufacturing Company, same place. Filed Nov. 15, 1897.
609,288. Means for Fastening Insulator-Pins to Cross-Arms. Loron Mitchell, Augusta, Ga. Filed May 10, 1898.
609,356. Electrical Conduit Box. Hubert Krantz, New York City. Filed May 6, 1898.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

TELEPHONE AND TELEGRAPH.

In an article on "Telegraphy and the War," the Washington *Post* says: "The telegraph system has become so perfect that the record of every operator in the service is immediately accessible to any manager of any office of any company. Should a telegrapher apply for work he would be required to fill out a blank, giving the name of his first employer, a list of the different offices in which he had worked and the reasons for having left his last place. The applicant is told to come back in an hour, at the end of which time the manager knows whether his record is clear or not. The enormous increase of telegraphic business as a result of the war brought numerous men of the 'hobo' genus to Washington. Some of these men are really expert telegraphers, but upon whom the whisky demon has fastened his grip. They are perfectly trustworthy as far as office secrets are concerned, and they do good work as long as they abstain from liquor, but sooner or later they give way to their craving for drink and are dismissed, to go to some other office, where they may be employed in an emergency, until they again fall before the tempter. An absolutely correct record is kept of such men, and it would be impossible for one of them to deceive a manager to whom he might apply for employment. There have been scores of them in Washington since the outbreak of the war, but they have gradually weeded themselves out, until to-day both of the great telegraph offices at the capital are manned by men who are as reliable in their habits as in their skill."

The Philadelphia Standard Telephone & Telegraph Company and the Chestnut Street Trust & Saving Fund Company have filed affidavits of defence in the suits brought against them, as principal and surety respectively, by the city of Philadelphia to recover on two bonds of $50,000 each, given as security that the Standard Company would put in operation a telephone system within a year from the date of approval of the company's plans, July 22, 1896. The defendants aver that all of the provisions of the ordinance were faithfully performed except that owing to the doubtful validity of the bonds issued and the inability to raise money on them it was found impossible to build the plant in the prescribed time. It is then contended that the sum of $50,000 named in the ordinance and in the bond upon which suit is brought is a penalty and not a sum named as liquidated damages; that the statement of claim is defective and insufficient to entitle the plaintiff to judgment, for the reason that the items making up the aggregate $50,000 alleged damage to the city are not set forth, and there is nothing in the statement to show the character of the injury done to the city or anything to show how a failure to supply the citizens with telephones has caused an injury of $50,000 to the city in its corporate capacity.

Representatives of the various companies in the Iowa Telephone Association, which embraces most of the independent lines, met recently in the Commercial Exchange rooms at Des Moines and revised the toll rates which have been in operation to the present date. The companies were represented as follows: Central Telephone Company —H. E. Teachout, J. W. Hill and M. McFarlin; Perry Telephone Company—Geo. N. Bandy; Jefferson Telephone Company—C. G. Cockerell; Spirit Lake Telephone Company—W. W. Pritchard; Boone Telephone Company—O. E. Wells; Marshall Telephone Company—W. G. Boone; Clearfield and Mt. Ayr Telephone Company—D. N. Smith; E. H. Martin Telephone Company—E. H. Martin; Conway Telephone Company—G. A. Haynie; Knoxville Telephone Company—J. S. Bellamy; Chariton Telephone Company—Mr. Stuart; Morovia Telephone Company—Mr. McFatridge; Hawkeye Electric & Commercial Company—C. W. Bartlett. The main feature of the revised tariff sheet is the fact that tolls will be based hereafter on mileage rather than the number of counties through which a message passes. The former plan worked very inequitably.

At Durham, N. C., when the Interstate Company, a local organization, began putting up a system, the Bell company gave a free service and continued to do so for about two years. In spite of this fact the new company was a success at regular rates. The Bell company has now taken another tack and issued a schedule of rates to correspond with those of the Interstate, and is making new efforts to regain its patrons, but the people of Durham are not in a humor just now to give the Bell system a very hearty endorsement, especially when the life of a home enterprise is at stake and after the treatment they have received.

A new telephone company has been organized at Aberdeen, S. D., under the name of the Central Dakota Telephone Company. It will build and operate a telephone line from Brookings to Pierre, with side lines branching out to all towns of any importance on either side.

A Spartanburg, S. C., correspondent writes: "The Home Telephone Company is moving ahead. Their organization has been completed and they will begin work at an early day. They have 200 to 300 subscribers here, who bind themselves to take these home 'phones five years to the exclusion of the Bell 'phones. They expect to begin with their service by the first of the year."

The opening of the new French cable between Havre and Cape Cod last week was marked by very friendly messages between President Faure and President McKinley and between the presidents of the Chambre de Commerce de Paris and the New York Chamber of Commerce. This line, which runs direct from America to France, is the longest and most expensive submarine cable ever laid. All other lines from America to France have relaying stations on British territory.

The North Park Telephone Company has filed incorporation papers with the Secretary of State at Denver, Col. The company has been formed to operate a principal telephone line between the town of Walden, in Larimer county, Colorado, and the city of Laramie, in Albany county, Wyoming, with branch lines to be established later.

The Mankato Citizens' Telephone Company has awarded the contract for installing a 200-'phone plant in Mankato, Minn., to H. M. Kellogg, for about $7,000. The contract is to be completed within ninety days. The stock of the company has been entirely subscribed by Mankato citizens, and important connections are to be made with other lines running north and south.

A local company on the plan of the Delmarvia Telephone Company has been organized in Reading, Pa., and has applied to the city council for a franchise. The members of the new company investigated the workings of the Delmarvia system at Wilmington, Del., and were apparently well pleased with it.

The Standard Telephone Company has completed its line from Kansas City to Marshall, Mo. The line will be extended to Cooper County and finally by way of Sedalia from Higginsville through Southwest Missouri and to St. Louis along the Missouri Pacific Railroad.

The Massillon, O., *Independent* says: "The Bell Telephone Company, which is now building metallic circuit toll lines to Canal Fulton, Clinton, Nimisila and other places west of the city, is preparing to extend its lines south through Richville, Navarre, Beach City, Wilmot and Justus."

The Oneida Telephone Company has brought suit against the Central New York Telephone & Telegraph Company for refusing to set up one of its instruments in the office of the Oneida Company's superintendent.

Lexington, Miss., is to have a telephone system, the result of the efforts of some of its young business men. The capital stock has been subscribed and thirty-eight subscribers secured.

The Des Moines Mutual Telephone Company will complete the first year of its existence on October 1.

New Companies Incorporated.

The Perry County Telephone Company, DuQuoin, Ill. Capital stock, $12,000.

The Midland Telephone Company, Adrian, Minn. Capital stock, $50,000. Incorporators: Dan Shell and others.

The Albuquerque-Bland Telegraph & Telephone Company, Albuquerque, N. M. Incorporators: Wm. T. Powers, B. Brooks, J. J. Dickey and A. L. Conrad.

The Trans-Mississippi Telephone Company, Omaha, Neb. Capital stock, $10,000. Incorporators: William B. Douglas, Warren P. Carlisle and W. P. Lathrop.

The Mountain Home & West Plains Telephone Company of Arkansas, West Plains, Mo. Capital stock, $5,000; capital to be assessed in Missouri, $450.

The People's Telephone Exchange, New Richmond, Wis. —to establish a telephone exchange in New Richmond. President, Charles N. Gorham; vice-president and manager, A. J. Presson; secretary, Wm. Hughes; treasurer, Dr. Epley.

The Telephone Information Company, Limited, East Orange, N. J.—to gather and distribute information of all kinds by means of electrical contrivances. Capital stock, $125,000, of which $1,000 is paid in. Incorporators: Henry B. McDowell, Howard K. Wood and Duncan T. McLaren, all of East Orange.

The Maryland Telephone & Telegraph Company, Baltimore—to operate lines in Frederick, Washington, Allegany, Garrett and Montgomery counties, Maryland; Adams and Franklin counties, Pennsylvania, and Loudoun county, Virginia. It is the intention of the company to purchase the interest of the Interstate Telephone Company which now conducts the principal telephone system in Frederick. Capital stock, $30,000.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

Abbreviations: crt. indb., certificate of indebtedness; coll., collateral; cons., consolidated; const., construction; conv., convertible; com., common; deb., debentures; exten., extension; gen., general; g., gold; guar., guaranteed; inc., income; imp., improvement; pd., paid; pfd., preferred; mtg., mortgage; tr., trust; A., annually; S., semi-annually; Q., quarterly; A. & O., Apl. and Oct.; F. & A., Feb. and Aug.; M. & S., May and Sept.; J. & D., July and Dec.; J. & J., Jan. and June.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 11⅞c.; Lake, 12c.; casting, 11⅝@11¾c.

The directors of the Troy (N. Y.) City Railway on the 18th inst. declared a dividend of 1 per cent., payable September 1.

The Street Railway & Illuminating Properties, Boston, has declared a dividend of $2 per common share, payable August 19 to stockholders of record August 16.

The Commercial Cable Company gives notice that the cable between Hong Kong and Manila has been repaired, restoring telegraphic communication with Manila.

The Niagara Falls Electric Railway Company has declared a quarterly dividend of 1 per cent., payable September 15. Transfer books close September 1 and reopen September 16.

The coupons of the first mortgage convertible gold bonds of the Edison Electric Illuminating Company of New York, due September 1, 1898, will be paid by the Guaranty Trust Company, New York, on and after that date.

The American Loan & Trust Company of Boston, as mortgage trustee, has applied to the United States Court at Fort Worth, Tex., for the appointment of a receiver for the Dallas Electric Company, interest on the bonds being in default. The property is said to be valued at $388,000.

War, instead of depressing stocks appears to have had the opposite effect in this country. Since war was inevitable between Spain and the United States up to the close of business last week the average price of twenty of the more active stocks had risen from 55.89 to 69.61—13.72 points.

The Metropolitan Street Railway Company of New York has declared a dividend of $1.25 per share upon the present capital stock of $30,000,000, payable October 15 to stock of record August 31. Transfer books close for cash dividend and for allotment of new capital stock on August 31 and reopen September 12.

The Edison Electric Illuminating Company of New York reports for July: Gross earnings, $196,400, increase $33,947; operating expenses and taxes, $112,348, increase $20,920; net earnings, $84,052, increase $13,017; depreciation charge, $17,500, increase $5,500; balance, $66,552, increase $7,517; accrued interest on bonds, $27,075; surplus for dividends, $39,477, increase $7,517.

The New Telephone Company of Indianapolis has made a mortgage to the Central Trust Company, as trustee, to secure $800,000 gold bonds in two series, the first consisting of $300,000 6 per cent. bonds, due in three years; the second series of $500,000 5 per cent. bonds, due in twenty years. The second series, it is stated, is to remain in the hands of the trustee until the first series matures, at which time $300,000 of the bonds is to be applied to the payment of the first series, and the remaining $200,000 to be used for extensions and betterments "then and thereafter necessary."

Justice Cohen of the New York Supreme Court has appointed James G. Graham of Newburg temporary receiver for the New Paltz & Wallkill Valley Railroad Company on the application of the directors for the voluntary dissolution of the corporation. The bond of the receiver was fixed at $50,000, and the order to show cause was set down for December 1 next. The total liabilities are $185,730, of which $150,000 are bonds; $35,530 to general creditors for materials and loans, and $200 due employes. The nominal assets are $154,196, the principal items being real estate, car equipment and power house machinery, $115,000; passenger cars, $13,000; other cars, $7,800; dynamos, $6,500; engines, $3,700.

The Philadelphia "Times" financial editor says: "There are few people today who would be willing to say the future of the United States has ever been brighter, more promising than it is at present. It is not necessary to point out why this is the case. One has only to read the daily papers to understand. Behind it all, however, is our success in this war with Spain. It is the basis upon which this country is to enter upon an era of prosperity such as we have never known. And Wall Street is now discounting as much of the business activity as it can see in sight, just as it did the approach of the war and its progress after hostilities had begun."

The Boston "Beacon" says: "Somewhat akin to the investment standing of our home railroads are the stocks of the two electric light companies which supply Boston and the citizens thereof with electric light, for these stocks, like those of the railroads, are non taxable to residents of this State. Of these two stocks, that of the Boston Electric Light Company has been unusually active during the past two weeks at constantly advancing prices. The rise has been aided by the annual report which shows that during the past year 6 per cent. dividends were paid, but that earnings amounted to some 14 per cent., from which $50,000, or say 3 per cent., were charged off for depreciation on plant accounts. The company thus earned 10 per cent. net for the year, with something to spare."

On his return from New York to Chicago last week, Charles T. Yerkes said there was "absolutely no truth in the stories of the consolidation of the North and West Chicago and the Chicago City street railway companies." Mr. Leiter makes a positive denial that his visit to the East had anything to do with street-car business. He said to a Chicago reporter: "The whole report is bosh. It is true that I went East, but I know nothing about a proposed consolidation of street-car interests. It was not for the purpose of discussing such a proposition that I went to New York, and nothing is further from my mind at this time. It can be said in positive terms that I am not connected with a deal to consolidate the North, West and South Side companies."

The Union Traction Company of Anderson, Ind., has become the owner by purchase and consolidation of the street railway plant in Anderson formerly owned and operated by the Anderson Electric Street Railway Company. This consolidation was completed July 1, 1898. The company has outstanding $300,000 of stock, all common, and has issued $600,000 of 5 per cent. bonds, dated July 1, 1898, to run 20 years, interest payable quarterly, both principal and interest payable in gold; $150,000 of these are left in trust with the Farmers' Loan & Trust Company of New York, trustees, with which to take up $150,000 of bonds outstanding, heretofore issued by the Anderson Electric Street Railway Company on the city plant at Anderson. The officers of the new company are: President, Philip Matter; vice-president, J. A. Van Osdol; secretary, Ellis C. Carpenter; treasurer, John L. Forkner; manager, Charles L. Henry.

The Brooklyn "Eagle" of Sunday has an article in which it expresses surprise at the recent advance in Rapid Transit shares and sees in the present outlook no good speculative reason for eagerness to purchase them at the latest quotations. The "Eagle" says: "The outlook for continued and largely increased earnings for the transit systems is also affected by the coming electrifying of both elevated roads. The Brooklyn Elevated Company is to electrify two of its lines and some twelve miles of its roadway this fall, and will be offering a sharp bid for increased business early next year. The entire system will be electrified shortly afterward, and the Kings County Railroad management has also pledged itself to the plan to use that method of propulsion in the near future and is now engaged in preparing to introduce it on a portion of its road in connection with bridge crossing. With the elevated companies offering quick and more frequent service, as they will be enabled to by this new system, there is no question that the street railroads will suffer and that their earnings will be affected."

ELECTRICITY.

Vol. XV. NEW YORK, AUGUST 31, 1898. No. 8.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4081 Cortlandt.

SUBSCRIPTION RATES:

United States,	$2.50
In Clubs of Five or More,	2.00
Foreign Countries,	4.50
Single Copies,	10 cents

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.
Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

The American Association for the Advancement of Science.

The Convention of the American Association for the Advancement of Science, which has just drawn to a close in Boston, and a brief report of the proceedings of which will be found elsewhere in this issue, was probably one of the greatest assemblages of scientists that have ever met in America. Almost every branch of science was ably represented by one or more delegates, not only from this country but from almost all the leading nations of the world. A number of prominent electricians and physicists were present, and presented papers of more than ordinary importance to the electrical profession. Almost all the topics touched upon, about 440 in all, were very timely and of exceptional interest. Several discoveries of great value have been brought to light, as many scientists had been waiting for such an opportunity to exploit their researches where they would be fully understood and appreciated. In the majority of cases these discoveries have been the result of years of profound investigation and patient toil. Dr. Brush's discovery of a new gas, which will probably form the base of a new group of elements, is unquestionably a triumph. Altogether, this Association should be congratulated for the excellent work it has accomplished at its jubilee meeting.

* * *

The Annual Convention of the American Street Railway Association.

The Seventeenth Annual Meeting of the American Street Railway Association, which will be held in Boston on September 6, 7, 8 and 9, promises to be one of the most successful gatherings in the history of this Association. Great interest appears to be taken in the Convention by all the leading street railway men in and around Boston, which fact alone should ensure an excellent attendance. The headquarters of the Association will be at the Hotel Brunswick, where it is understood a number of leading manufacturers propose to exhibit various street railway appliances. The Convention will be called to order by the President of the Association, Mr. Albion E. Lang, at 10 A. M. on Tuesday, September 6, at which meeting several interesting papers will be read, among others one on the "Municipal Ownership of Street Railways," which should prove of interest. On the following day the Convention will meet at 9:30 A. M. At each session two or three papers will be read, which, judging from their titles and the names of the authors, should be valuable additions to the existing literature bearing on subjects of interest to street-railway men. The afternoons will mostly be given up to excursions to points of interest in Boston and neighboring towns, and on Wednesday the members and their guests will partake of a clambake at Nantasket Beach. The annual dinner, which has invariably proven one of the most enjoyable social features of former Conventions, will be given at the Hotel Brunswick at 7 P.M. on Thursday.

As a large number of ladies are expected to be present, special arrangements have been made looking to their comfort and enjoyment while the technical papers are being read and discussed. The programme for the women includes a trip to Bunker Hill monument and various other points of historic interest as well as a drive through the Park, while on Friday morning a shopping trip is planned which will include a visit to the principal stores of the Hub. Altogether the coming Convention promises to be most instructive and enjoyable.

* * *

Another Alleged Invention for Seeing by Electricity.

If we are to believe all that we hear, there should be some wonderfully novel sights to be seen at the Paris Exposition of 1900 in the section devoted to electricity. There is Szczepanik with his telectroscope for seeing by electricity, for which it is claimed he has been paid an enormous sum of money and of which so little is really known. Now a rumor is spreading that Szczepanik's telectroscope is to have a formidable rival at this Exposition in an instrument invented by a Frenchman by the name of Dussaud. This new marvel, which, according to its inventor, embodies all the advantages of Szczepanik's apparatus, may furthermore be attached to an ordinary telephone circuit, and thus is said to enable one to hear as well as see. As in the case of the Polish school teacher's telectroscope, no one appears to know exactly how the Dussaud apparatus works or upon what principle it is based. It is described in a recent edition of the New York *Herald* as follows:

"The instrument consists of a camera, at the opposite end to the lens being a revolving screen worked by clockwork and pierced with small openings arranged in spiral form. Behind this is a system of selenium layers connected with a battery whose current traverses them, and also the primary circuit of the induction coil. By means of this machine an observer at the receiving station sees on the screen the exact image produced in the camera of the transmitter."

The above explanation is altogether too vague to give one any idea of how the alleged apparatus works. It would appear however to be designed on very much the same principles that have been tried over and over again without success by inventors

both in this country and abroad. It might therefore be well to warn those who visit the great Paris Exposition not to expect too much from either Szczepanik's or Dussaud's instruments. It will be a case of "seeing is believing."

* * *

Promoting Our Export Trade With South America.

Among the measures that will come up for consideration at the next session of Congress is one that is of great importance to exporters in general and to exporters of electrical machinery in particular. The measure in question is the proposition to incorporate an International American Bank for the purpose of promoting export trade. A bill with this object in view was introduced at the last session of Congress and passed the Senate, but failed to pass the House, being crowded out by several other important measures. It has however been made a special order for the next session, when it will be brought up and undoubtedly speedily enacted into a law.

The bill is in accordance with the recommendation of the Pan-American Congress, and is designed to furnish such banking and exchange facilities as will promote trade between the United States and the countries of Central and South America. The bill provides that the bank shall have a capital stock of $5,000,000 with the privilege of increasing it to $25,000,000. The institution, in accordance with the terms of the bill, shall be under the supervision of the Comptroller of the Currency, and in the charter of corporation which the bill grants certain privileges are accorded the incorporators in view of the advantages which are expected to accrue to those interested in trade with the countries referred to above.

The people of the United States in common with those of the Central and South American republics naturally feel the importance of increasing commercial intercourse between the different portions of the American Continent, and believe the development of such intercourse has heretofore been retarded by lack of adequate facilities for exchange between the several countries, and their hope for a revival in trade is based upon the establishment of improved banking facilities which will emancipate these growing countries from their long servitude to the bankers of London and Continental Europe. No one has expressed the situation more aptly or forcibly than Mr. Theodore C. Search, president of the National Association of Manufacturers, after a tour through South America, when he said :

"As in our ocean commerce, so also in our financial relations with other countries we are dependent largely upon the services rendered by foreign interests. Particularly in our dealings with the nations to the south of us we are in urgent need of direct international banking facilities. We do $150,000,000 worth of business with South America in a year, and yet all our balances have to be settled through English or European banking houses. In the great trade centers of South America the English, the Germans, the French and the Italians have their banks, but I think I am right in saying that there is not an American bank in all South America. Manifestly this is a serious hindrance to our trade."

It is unquestionably true that the financial part of all our business with South America is carried on through Europe. Foreign vessels carry the goods, Europe receives the commissions and freights, and furthermore sells most of the goods consumed in South American countries, while the United States is the largest purchaser. This condition of things is undoubtedly due to five facts : First, we have no banks in South America; Europe has them everywhere. Second, we run few steamships to South America; Europe runs them to all its ports. Third, we have no United States stores in South America; Europe has her stores in all parts of that continent. Fourth, we sell for cash; Europe gives credit. Fifth, Europe makes goods and packs them to suit the South American trade; we do not.

Without underestimating the importance of the other facts named, it is quite obvious that the first one is at this time pressing with great urgency upon the attention of American manufacturers in connection with the desire to increase our commerce with our southern neighbors.

Under the Searchlight.

Notes and Comments on Various Topics.

IT is stated that the quarter of a million dollars spent by the Montana Power Company in the construction of the Big Hole dam has been lost to the promoters of the enterprise, as the whole structure, damaged by a flood, will have to be rebuilt from the foundation up. We believe this is one of our old friend Byllesby's enterprises, and if we mistake not, at the time of its conception we remarked that Big Hole was a very suitable name for a project in which Byllesby was a leading spirit, as the investors in it would discover. This is another of our predictions that have been fulfilled to the letter, and still we lay no claim to the gift of prophecy.

* * *

A Novel Bee Hive.

A lineman belonging to the telephone company of Flushing recently climbed one of the 60-foot poles belonging to the company with a view to adjusting some of the wires in the box at the top of the pole. To his surprise he found that a swarm of honey bees had made the box their home. By the aid of a torch made up of rags he managed to finally smoke them out, when he was rewarded by finding several pounds of excellent honey.

* * *

REFERRING to the recent reduction in capital stock of the General Electric Company, the Boston *News Bureau* of August 24 says :

There have been deposited with the American Loan & Trust Company to date 9,200 shares of the preferred stock of the General Electric Company in opposition to the directors' capital reduction plan.

The indications are that there will be no compromise of differences existing between the directors and the preferred stockholders' committee, and that the matter must await the court's disposition.

The next step in the proceedings will be the filing of the answer to the bill brought by counsel for the committee, after which the court will set a date for a hearing—probably in November.

At the adjourned meeting of the General Electric Company, it is understood that of the 15,000 shares of preferred voting in favor of the proposed capital reduction, approximately 10,000 shares were represented by the Ames estate.

* * *

THE longest span of telegraph wire in the world is said to be in India across the river Kistna. It is over 6,000 feet in length.

* * *

THE *Engineer and Iron Trades Advertiser* of Glasgow gives the following useful hints as to the handling of electrical machinery and conductors :

Never touch an electric wire that has fallen down across your way while standing on the ground, as your body will become a conductor for the electric fluid to the earth unless you have rubber boots on. Linemen are sometimes seen pulling wires about, but they have insulating boots on their feet or rubber gloves on their hands. Some people, supposing these coverings to be only used for the protection against wet weather, have foolishly grasped wires and received severe shocks in consequence. Electric wires should be handled one at a time. If it is necessary to take hold of two wires at the same time, don't do it. In handling or drawing any wire lying over any of the ordinary street wires, especially such as convey currents for electric lighting, use a dry hand line for the purpose or grasp the wire with insulated pincers. An ordinary wire clothes line may become the conductor of a deadly current. In a dynamo room touch not, taste not, handle not. The most inoffensive looking dish-pan may strike you like a mailed hand. Nothing is safe to you here unless you know everything. Let working men remember that when a company has strung wires on the crossbars of poles so closely together that a man cannot move easily between them, it is better for him to come down and resign. What profiteth a man if he has a situation if his wife be a widow? Never close a circuit without giving notice to all concerned. A telegraph notice received in the back of the neck generally arrives too late to do any good. On no condition let two wires touch your body at the same time. Don't think that any wire is not dangerous. There is a difference between a gun with a cap on it and one without that can be detected with the naked eye, but a loaded wire —who knoweth it? Trimmers employed to attend to lights in public crowded thoroughfares should be sure that the current is turned off before they touch the lamp, as the stepladders are often very high and the public object to being hit on the head by a gyrating galvanized lamp trimmer.

* * *

IT is refreshing even to write of snow just now, so it is interesting to note that in Switzerland even after an ordinary snowfall, or during frost, the snow or ice deposited on the telephone wire equals fifteen times the size of the wire. At Zurich it reached as much as thirty times that of the wire, and the weight on a span of 100 meters would thus have a snow weight of 132 pounds. A post supporting 250 wires would therefore require to support a weight of 15 tons.

* * *

AN Eastport man, it is stated, contemplates purchasing the plant of the Electrolytic Marine Salts Company at North Lubec and turning it into a sardine factory. No one will enjoy the humor of this evolution of his gudgeon factory more heartily than Jernegan himself.

A LESSON IN WATERED STOCK.

(From the Buffalo Enquirer.)

A paragraph in the news columns says the General Electric Company has scaled down its stock 40 per cent., which means that every person who formerly held one hundred shares now has sixty.

About eight years ago the Thomson-Houston Company and the Edison Company consolidated and capitalized at fifty millions. It was given out widely that stock in the new trust would pay 6 or 7 per cent., inasmuch as the two companies controlled practically the entire electrical business of America. If you looked into the matter you found out that the money actually represented by the combined plants was less than ten millions. There were over forty millions of water in the stock. But you were shown that the business of the two companies practically warranted it, as they had been earning over 10 per cent. and of course would earn more after the consolidation.

So the lambs came in and bought and the kind-hearted managers of the consolidation generously sold. Widows bought for investment. Foolish trustees put their trust funds in it. Speculators went into it expecting it to rise. They were all let in on the ground floor soon after the consolidation when the stock sold in the neighborhood of one hundred.

But, of course, even a great combination like the General Electric Company was no more able to suspend the laws of trade than you are to stop Niagara Falls. It is fixed unalterably that a business with good management can earn a normal dividend upon the money invested in it, no more—that is, for any considerable time. This must be so, because when you see one man enjoying a good thing you go in for it, too. Then somebody else does likewise, and directly the first man's capital can only make a normal earning, because he has to sell at the same prices you sell at.

When the General Electric Company came face to face with competition it could not earn a cent on the many millions of water which it was carrying, and the stock tumbled down to about thirty. It has been there ever since, and it is going to stay there, as is admitted by the action of the directors in scaling down the capitalization 40 per cent.

Nearly twenty millions of water have been wiped

out, and the people who paid $100 a share for it now have stock purporting to be worth sixty dollars which is really worth about thirty.

The question is, where did that thirty millions of hard cash go? The kind-hearted manipulators alone can answer. The lambs, the widows and the foolish speculators who were let in on the ground floor are still there, fleeced of two-thirds of their substance. This happened because they did not understand that you cannot make the water in a manufacturing stock worth par by buying it at that price.

What happened to General Electric and Cordage is likely to happen to Glucose and is not unlikely to overtake Buffalo City Gas. Financial water, like that in Lake Erie, seeks its level, and that level is zero.

MEETING OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

In Boston on the afternoon of August 22 the nine different sections of the American Association for the Advancement of Science met, and were addressed by their respective vice-presidents.

The papers read were upon subjects connected with the work of each particular section, and in almost every case were of special merit. In the section of Chemistry the Vice-President, Dr. Smith, professor in the University of Pennsylvania, presented a paper on "The Electric Current in Organic Chemistry." In this paper Prof. Smith traced the origin and growth of the use of the electric current in this branch of chemistry, paying special attention to some of its industrial features.

Another paper of interest to electricians was presented by Prof. Morley of Cleveland. The paper dealt with the question whether a magnet affects the velocity of light which passes through the field of its attraction. With the apparatus used it was shown that the passage of the current had no straining effect upon the optical portion of the instrument. Coils were used through which the current could be sent at will, and it was demonstrated that the change in intensity of the current had no appreciable effect either to retard or accelerate the wave length of light.

On Tuesday, August 23, the programme for the day was rather a heavy one, comprising meetings of the sections in the morning, several excursions to points about the city and receptions by the clubs in the evening.

The council met as usual at 9 o'clock, and after an hour's interval came the meetings of the various sections. At some only three or four papers were read, but at others the number ran up to thirty or more.

Three auxiliary associations had meetings on Tuesday, the American Chemical Society, the Geological Society, and the American Forestry Association.

Probably the most important announcement of the day was made by Mr. Charles F. Brush of Cleveland, who described at length a discovery made by him of a new gas, a constituent of the atmosphere, which he has provisionally termed "Etherion."

In the afternoon the excursion most largely attended was that about Boston Harbor. About five hundred persons were on the boat.

In the evening Mayor Quincy gave a complimentary dinner to the officers and guests of the Association. Several toasts were responded to by prominent men and the occasion was thoroughly enjoyed by all. Among the foreign guests present at the banquet were Prof. Charney, delegate of the French Government; Prof. Conrad Cooke and Prof. Benj. Howard of London; Prof. Galbraith and Prof. Blue of Toronto, and Mr. Paul du Chaillu, the African explorer.

Notwithstanding the oppressive heat on Thursday, the scientists began to gather at the Rogers Building very early, all having evidently enjoyed themselves on the excursion to Salem on Wednesday. The council of the Association after a long session elected Prof. Edward Orton, State Geologist of Ohio, President for the coming year. Columbus, O., was decided upon as the meeting place of the Association for the next Annual Convention.

As many as one hundred papers were presented at the various sectional meetings on Thursday, many of which were of great importance.

Prof. Guthrie read a paper before the section on Physics on a "Redetermination of the Ampere" which especially attracted a great deal of attention.

Several of the sections had their final meetings on Thursday, finishing the work allotted them.

In the afternoon Governor and Mrs. Wolcott gave a reception to the scientists and extended to them the privilege of inspecting the grounds of the palatial residence of the Governor at Milton Hill.

With Friday the work of the Association began to draw to a close. The members went to Harvard University by special invitation of the President and Fellows of the college and were royally entertained.

Only two sections held any meetings on Friday, the principal one being that of the physicists. The papers were mostly very technical, the most important one being "A Calorimetric Determination of the Energy Dissipated in Condensers," by Prof. A. N. Smith, of Wesleyan.

On Saturday most all the sections had completed their work, the last general session of the Convention being held at 10:30 A. M. Many scientists whose names are familiar the world over were upon the platform.

Reports showed that 903 delegates had registered as members of the Convention, 158 being from New York. Canada, England, France, Germany, Brazil, Mexico, Japan and Australia were each represented by one or more delegates, there being in all 443 papers read. Resolutions were passed tendering the thanks of the Association to Governor Wolcott, to Mayor Quincy, to the people of Boston and to all who had taken any part in contributing to the pleasure and comfort of the delegates.

Annual Convention of the Street Railway Association of New York.

The Sixteenth Annual Convention of the Street Railway Association of New York will be held at the Manhattan Beach Hotel, Coney Island, on September 13 and 14. It is expected that the attendance will be quite large, nearly 300, and the programme arranged will undoubtedly be satisfactory from a social as well as a business standpoint. The locality is one of the most delightful that could have been selected, and the names of the committee of arrangements are a guarantee that full consideration will be given to every detail calculated to gratify either the social or the business inclinations of our enterprising street car men. This committee is composed of President C. L. Rossiter of the Brooklyn Heights Railroad, President Albert L. Johnson of the Nassau Electric Railway, and President J. L. Heins of the Coney Island & Brooklyn Railroad Company.

The papers to be presented will be on practical subjects connected with the operation and management of street railways and with other things of special interest to street railway owners and officials. As a portion of the social programme of the Convention, the committee has arranged for a formal dinner to take place in the Manhattan Hotel on the evening of September 13. All the members will be present on this occasion and there will be the usual toast-making and speeches.

The president of the New York Street Railway Association is G. Tracy Rogers, president of the Binghamton Railroad Company, and Henry A. Robinson, attorney for the Metropolitan Street Railway Company of New York, is secretary and treasurer.

AMERICAN STREET RAILWAY ASSOCIATION CONVENTION.

Programme.

The following is the official programme of the Seventeenth Annual Meeting of the American Street Railway Association, to be held in Boston from September 6 to 9 inclusive:

TUESDAY, SEPT. 6.

10 A. M. Meeting called to order by Albion E. Lang, President.

Calling of the roll.

Address of the President.

Report of the Executive Committee.

Report of the Secretary and Treasurer.

Reading of paper on "Comparative Earnings and Economy of Operation Between Single and Double Truck Cars for City Use," by Richard McCulloch, Electrical Engineer Cass Avenue and Citizens' Street Railway Companies, St. Louis, Mo.

Reading of paper on "Municipal Ownership of Street Railways."

Afternoon.—Trip to Concord and Lexington.

Evening.—Reception at hall.

WEDNESDAY, SEPT. 7.

Convene at 9:30 A.M.

Reading of paper on "Maintenance and Equipment of Electric Cars for Street Railways," by M. S. Hopkins, Electrician Columbus Street Railway Company, Columbus, O.

Reading of paper on "Carrying of United States Mail Matter on Street Railways," by W. S. Dimmock, General Superintendent Omaha & Council Bluffs Railway and Bridge Company, Council Bluffs, Ia.

Appointment of Committee on Nomination of Officers and selection of next place of meeting.

Morning.—Ladies to be taken to points of local and historic interest.

Afternoon.—Excursion down the harbor.

Clambake at Nantasket Beach.

THURSDAY, SEPT. 8.

Convene at 9:30 A.M.

Reading of paper on "To What Extent Should Street Railway Companies Engage in the Amusement Business," by Walton H. Holmes, General Manager Metropolitan Street Railway Company, Kansas City, Mo.

Reading of paper on "Inspection and Testing of Motors and Car Equipments by Street Railway Companies," by Frederick D. Perkins, Electrical Engineer Toledo Traction Company, Toledo, Ohio.

Election of officers.

Morning.—Drive through the Park for the ladies.

Afternoon.—Trip to Plymouth.

Annual dinner, Hotel Brunswick, 7 P.M.

FRIDAY, SEPT. 9.

Convene at 9:30 A. M.

Reading of paper on "Cost of Electric Power for Street Railways at Switchboard, both Steam and Water," by R. W. Conant, Electrical Engineer Boston Elevated Railroad Company, Boston, Mass.

Report of Committee on Standing Rules for Government of Conductors and Motormen.

Unfinished business. Installation of officers. Adjournment.

Morning.—Shopping trip for the ladies, visiting principal stores.

Afternoon.—Trolley excursion to Norumbega Park.

Shocking Accident in the Alps.

As we go to press a cable from London announces the accidental death in Switzerland of John Hopkinson, "the celebrated English electrical engineer," and that of his son and two daughters. From the meager information at hand, we learn that the party started out on August 27 from Arolla, in the Canton of Valais, to ascend the Dent Vesivi without a guide. As they did not return at night a searching party was organized, with the result that all four bodies were found at the foot of a precipice over which they had fallen.

LONDON NOTES.

[From our London Correspondent.]

Electric Tramway Systems.

That it is anything but an easy thing to secure permission to use electricity on numerous English tramways is clearly proved by two recent instances. The Bristol Tramways & Carriage Company and the London United Tramways Company have for several years been having a hard fight, and now they are both to be congratulated upon having won that for which they fought, but only after protracted negotiation and expensive procedure. As regards Bristol the facts are: In 1895 the company equipped part of its system of horse trams with the overhead trolley, and after a few months it was found that the economy and success were so great that there should be no delay in equipping the entire Bristol service in a similar way, and also it was arranged for various extensions. The company applied for powers, but the municipal authority had its eyes open to business and after considerable discussion arranged that the company should not be allowed to carry out its wishes unless it agreed to take the necessary electric power for the purpose from the municipal electric lighting works. For obvious reasons the company refused to fall in with these suggestions. It stuck to its guns with great determination, and has at last succeeded in getting Parliamentary powers for the purposes mentioned. The officials are at the present moment drawing up their plans for the reconstruction of track and the erection and equipment of a central power station which will be situated at Counterslip. New capital for these purposes will be raised to the amount of $1,250,000.

It will probably be remembered that in 1896 English rope-driven plant was turned out of the Bristol Company's St. George's power station and American direct-coupled machinery was installed in its place. There would therefore seem some probability that American generators and apparatus will be required for the new power house. It is hoped to have the entire Bristol service operated electrically before the end of the year 1899, so that some contracts may be given out before very may months have passed.

The other company that has succeeded in securing powers to install the trolley system is the London United Tramways Company. The company will in all probability be engaged equipping twenty miles of tramway on the trolley method in some of the suburban districts of London. And judging from plants which have been put down by the moving spirits in this company for other lines in England during the past year or two, there is every indication that American machinery and apparatus may be expected to predominate.

CANADIAN NOTES.

The town of Dundas, Ont., will give a franchise for fifteen years to an electric lighting company, of which Geo. H. Harper is managing director, the town to have 150 incandescent lamps and four arc lights.

The proposed electric railway between the towns of Lanark and Perth, Ont., is being revived. The subscribed capital is now said to be sufficient to build the road, and the company undertakes to complete it by the first of April next.

The West Kootenay Power & Light Company is now delivering 1,000 horse-power in Rossland, B. C., from its generators at Bonnington Falls, 30 miles away.

A number of Montreal gentlemen have purchased a mountain at St. Bruno, in the Chambly district, about 10 miles from Montreal, and propose spending a large sum in improvements. An electric railway from Montreal to St. Bruno is included in the plan.

Another very heavy transaction in electric property is on foot in the province of Quebec. Following the absorption of the Quebec District Railway Company by the Quebec, Montmorency and Charlevoix Company, the latter is about to acquire the property of the Montmorency Power Company, which furnishes the city with electric light and the street railway cars with their motive power. It is understood that the purchase price is $1,250,000. A meeting of the Quebec, Montmorency and Charlevoix Electric Railway Company will be held on the 13th of September next to ratify the purchase. The shareholders of the power company will receive a handsome premium on their stock, which will be 25 per cent. of its value in cash, while they will also raise in the stock of the Quebec, Montmorency and Charlevoix Railway an amount equal to their stock in the Montmorency Power Company.

Mr. Henry Symons, Q. C., has recently returned from England where he had estimates prepared for the construction of the proposed works of the Welland Power & Supply Canal Company. This project involves the construction of a canal from the Welland river to the brow of the mountain at Thorold, Ont., a distance of 8 miles; the construction at Thorold of a power house, and from Thorold to Lake Ontario a raceway by which to carry water into the lake. In addition to these different works estimates were obtained for the construction of a transmission line from Thorold to Toronto by way of Burlington Beach. The estimates obtained by Mr. Symons were prepared by Dr. Hopkins, F. R. S., one of the leading electricians of Great Britain; Sir Douglas Fox, Edmund Wragge, late of Toronto, and W. C. Unwin. The estimate for the machinery to generate 100,000 horse-power is £125,000; for transmission line to Toronto at a voltage of 10,000 and delivery of 50,000 horse-power, £801,600; for excavation and other work connected with the undertaking, £1,525,062. The total estimate therefore amounts to £2,452,162, or roughly speaking, $12,000,000. If the amount to be delivered in Toronto is reduced to 20,000 horse-power the project would cost $1,000,000 less. S. Pearson & Son, contractors, state that if the contract could be secured from the cities of Toronto and Hamilton for a considerable quantity of power for a definite term there would be little difficulty in raising money for the project by bonds and shares in Great Britain.

MINE SIGNALS.*

In a paper read by Mr. Clements before the South African Society of Electrical Engineers, attention is drawn to the various systems of signaling. The old-fashioned system is, of course, the hand-pulled rope and bell, or flapper, as used so much to-day in English coal mines, the difficulty of which is that in very deep mines there is apt to be an uncertainty in its indications, and the engine man cannot always tell if each pull of the rope has produced a sound. In America a pneumatic system is used, consisting of a line of pipe and an air cylinder about 6 inches in diameter by 9 inches long, with a piston movable by a lever which is employed to give a sudden push of air down the pipe line to blow a whistle all over the system. The pipe used is recommended to be at least 2½ inches, and even more for long distances. The pipe should be smooth inside, as it can then be talked through, which is not possible with rough pipe, although signaling can be effected through rough pipe. Though by no means perfect, electrical signaling seems to be, on the whole, the best.

If there are, say, balanced skips for which to arrange signals, there are three wires run down the shaft, two being connected to the poles of a battery, and the third, or middle wire, being used to connect all bells in series and ring them simultaneously when a circuit is made through any push on the system. All bells are, of course, to be placed between the middle wire and the same pole wire, and the pushes between the middle and other pole wire. A separate signal should be arranged from the pit mouth to the engine room, and vice versa, for the driver could not otherwise tell whence the signal comes, whether from the top or the lower set of skips.

A bell at the pit mouth keeps the banksman informed as to what the skips below are doing. Communication with the signals below must only be possible via the engine driver's apparatus. The chief disadvantage of the system is, that the driver has no means of knowing the places of the skips except by the correctness of the signal given, but the author has never known of an accident, as the bells ring simultaneously through the mine when rung from any one place, and those at any level know thereby where the skip is and what it is doing.

In a second system a separate wire is run to each level, the two battery wires being run to each level also, and when a signal is sounded it rings only the bell at the one place and a bell or indicator at the mouth and in the engine room. This system simplifies the code of signals; the driver knows what he is doing, but the cost and complexity are increased. The first system is that which the author advises. The wires may be run in either iron pipes or wooden conduits of deal two-eighths in thickness, run along the roof timbers in an incline, and coated in and out with coal tar, the wires, No. 18 S. W. G., and lead covered, being held in position by wooden cleats, and all bells and pushes being placed in wooden boxes. This system worked well for eight months, after which the settling of the shaft so stretched the wires that they broke, though no further trouble has since arisen. Though exposed to much acid water, the lead-covered wires had not been affected.

When conveyed in iron pipes trouble has been found from internally condensed moisture, and from grounding of the wires in the pipes.

The Robinson Deep and the Simmer and Jack discarded a pipe system, and installed a bare copper wire system on double petticoat insulators of porcelain. But little trouble has been experienced. The wires should be at least 7/18 S. W. G., and they should be shackled off at distances of each 100 feet, and a bight made in the wire to run off moisture. Below a bight in the shaft the wire continues, not directly underneath the length above, but to one side. Armored cables should be pure rubber, insulated with a lead covering to the conductor and a steel wire sheathing. Such a cable can be bent round corners without injury to any part. In vertical shafts it may be hung well up in a corner of the ladderway, and in inclines in an upper corner of the skipway. The author considers that armored cable is the best for signaling purposes. He considers that one quadruplex cable is fully as good as a pair of duplex cables, i. e., one for the pole wires, and one for the two middle wires. Steel-sheathed cable may carry its own weight in vertical lengths of 300 to 400 feet, the connections between the lengths being in watertight boxes.

At pump stations or landing stages, cable should be boxed in for 10 or 12 feet above landings, and no inclines cable ought to be removed from the risk of having hung on it lamps, tools, etc., and general precautions taken against injury.

There is no satisfactory signal bell known to the author. Pushers, in general do not give satisfaction. The galvanometer key is better. Pulls, likewise, are apt to be unsatisfactory, as they depend on springs, which are apt to fail by rust. For batteries the secondary cell is preferable for cleanliness and compactness. The Leclanché primary is satisfactory if properly attended. Whatever form be employed, there should always be an auxiliary. The EMF. should range from 6 to 16 volts.

Bells and pulls must be inspected weekly at least, and all contacts kept bright.

* From the *Electrical Review*, London.

NOTES ON THE ELECTRO-CHEMICAL TREATMENT OF ORES CONTAINING THE PRECIOUS METALS.*

BY MAJ.-GEN. C. E. WEBBER.

(*Concluded from page 103.*)

In the latter half of 1894 J. H. Haycraft of Adelaide, in West Australia (whose invention jointly with Breakell has been already mentioned), described an improved process for the treatment of auriferous and argentiferous ores. He expressly disclaims originality for the apparatus, and for any separate part of his process, or for any two or more parts together, but considers that his invention consists in the entire and particular combination planned by him.

In this process we again find the following conditions: One circular vessel for the whole process of treatment, having a revolving stirrer with projecting arms connected with the positive pole of a dynamo. The charge under treatment is a mixture of pulverized ore and water, and the precipitation is obtained by the use of a solvent in conjunction with the electric current, the precious metal being absorbed (and afterwards recovered) by amalgamation in mercury. But, in addition, the process presents the following features:

First, the vessel is heated by a furnace or by a steam chamber underneath, and being therefore of metal, the whole of it forms the cathode.

The stirrer, which is the anode, can doubtless be insulated from the vessel without much difficulty, and its arms are clad with carbon electrodes at their extremities, which in revolving are separated from the cathode by a space of about a quarter of an inch.

To the charge of ore is added about 5 per cent. of its weight of mercury, with about 1 per cent. of chloride of sodium or any other salt capable of yielding chlorine by electrolysis; but these proportions the inventor varies according to the class of ore under treatment.

Very little practical experience in working an apparatus of the description given by Haycraft might be expected to fail in three out of many difficulties that the construction presents, namely: (1) in keeping the density of the solution uniform throughout; (2) in bringing it under the influence of the current within the one-fourth inch space between the anodes which lie nearest to the cathode, where the path of the greater part of the current would lie; and (3) the difficulty of maintaining surface parallelism between the electrodes.

In September, 1894, P. Danckwardt patented in the United States an improved apparatus for and process of extracting gold and silver from ores.

In this we find again the treatment of finely pulverized ore in a solution containing potassium cyanide —in this case about 10 lbs. of cyanide to the ton of ore—and agitation. Besides, the inventor adds to the solution 2 to 3 lbs. of ammonium, "or another alkali," sulphide, the object of which is said to be to reduce the consumption of cyanide to a minimum, as a means of preventing "the formation of soluble combinations between any of the raw metal combinations and part of the cyanide of potassium."

The agitation is effected by the rotation of a cylindrical drum A on its axis, and two ways of doing this are described. In one case (Fig. 7) the rotating drum is external to the inner one, and the conditions are the other way in the second example (Fig. 8). In each case the cylinder in motion, B, constitutes the anode, the stationary vessel the cathode. In the first case the outer revolving drum carries internally blades, *k*, *k*, by which the solution is stirred and guided on to the amalgamated surface of the inner fixed cylinder B, which is made of copper.

The second example (Fig. 8) of effecting agitation in this way is an auxiliary one, and only resorted to in case the extraction by means of the first form of apparatus is imperfect, when the solution taken from the first having been filtered is passed through one or more of the agitating vessels; and in this latter case the outer and stationary tanks, A, A, besides being amalgamated on their inner side, contain a little mercury, M, M.

In spite of the low tension of the current employed the difficulty of insulation between the cylinders at their axial bearings must be considerable. I can find no record of this combination having ever been used on a practical scale, and I do not think that the description given is such as to enable an apparatus

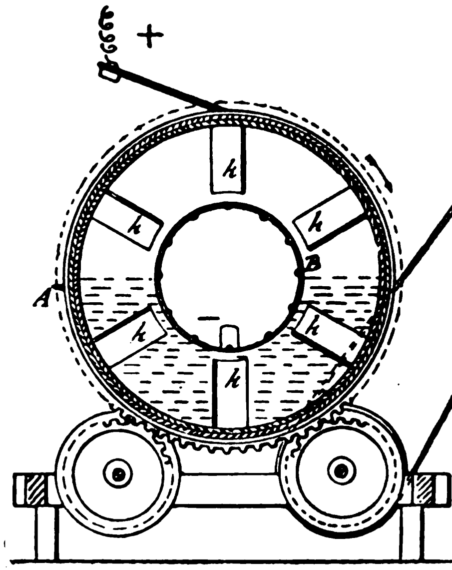

FIG. 7.

to be constructed that would produce practical results on a working scale. The actual subjection to electrolysis of the mixture described was, of course, not novel in 1894.

Edward W. Clark filed an application in the United States in November, 1894, describing a process and apparatus, which he calls an "electric chlorinator," for extracting ores by electrolysis.

He passes an electric current through a solution containing the crushed ore to be treated and chloride

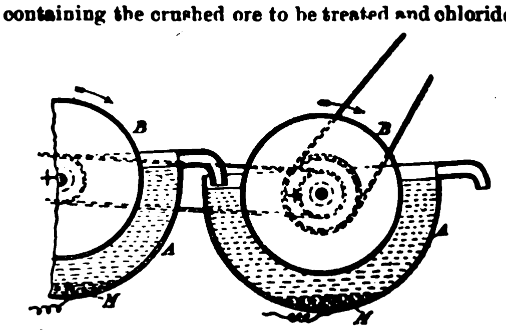

FIG. 8.

of sodium. He uses an agitator of a particular form, and mercury as his cathode.

The vessel in which the agitation takes place is a horizontally fixed cylinder, A, with a shaft B, carrying spirally fixed stirring arms, C, which revolve inside on its axis. The bearings are gas and water tight.

The anode is a fixed carbon lying on the bottom of the cylinder. The mercury cathode lies at the bottom of small boxes, D, D, attached in pairs at intervals on each side of the cylinder. The communication between the cylinder and the boxes is by means of openings, E, E, at the lower sides of the former, which are covered with a canvas screen or filter. The current has to pass between the electrodes through these screens, in company with the solution on its way for the chloride of gold to deposit the gold in the above-named boxes or amalgamating chambers.

With the exception of that part of the combination which is effected by the special form of apparatus, and which is said to prevent the combination of the liberated hydrogen, oxygen and chlorine, there is no reason for claiming novelty for the invention.

At the end of 1896 Dr. Keith, who read a paper on "The Electrolysis of Gold," in March, 1895, before this Institution, took out a patent in Canada, in which he makes, amongst others, a claim for a "process of extracting gold and silver from auriferous and argentiferous materials, rocks or ores, which consists in submitting them to the solvent action of a solution of cyanide of potassium, containing a solution either of cyanide or bromide of mercury, or both, and then depositing the gold or the silver, or both, and the mercury from the solution so obtained, by means of electricity upon a cathode or an amalgam."

I understand that this was reported on by Prof. Silvanus Thompson, but the only encouragement I can find in the published part of his report is, that the "process hastens the solution of the gold, in comparison with the use of potassium cyanide only."*

I now propose to go more carefully into the process I have described as that of Messrs. Pelatan-Clerici, which I have had under my observation for more than two years.

It claims as its object the treatment of ores containing gold or silver, or both, so as to obtain the precious metal therefrom in a manner more complete, simple, satisfactory and with greater economy of the agents, than hitherto.

As an example, I shall refer to the simplest form. The improvements are:

First, that the space (unlike some previous proposals) between the revolving anode and cathode is free from all obstructions, the disadvantages of which are that they tend to cause the ore under treatment to accumulate upon the cathode and prevent perfect parallelism between the surface of the mercury cathode and the effective under surface of the anode —a condition the necessity for which is obvious.

Second, that the sludge is constantly and gently swept by the current from over the cathode so as to have no tendency to settle on it, and also so that that portion of the sludge which is above the anode should not acquire such a continuous rotatory motion as to cause the heavier particles to be carried outwards by the centrifugal action, and thus to travel round in the same plane, instead of in their turn being subject to the combined action of the electric current and the chemical agents employed.

This leads me to draw attention to the necessity that efficient agitation should, in the first place, maintain the sludge perfectly homogeneous throughout its mass, and in the second place, should not be such as to disturb or break up the mercury cathode. In the example before us this is secured by regulating the speed at which the anode is driven, according to the size of the vat and the number and length of arms that are attached to the shaft, either for the support of the anode plates, or to act only as stirrers. For instance, subject to the density of the sludge, it is found that, if the speed of the agitator has to be lowered 30 per cent., the number of arms should be doubled.

As the diameter of a vat is increased, in order to maintain homogeneity in the mixture the rate of motion at the periphery of the agitator would have to be increased, but to the detriment of the surface of the mercury cathode, namely, above a rate of about 8 to 10 feet a second. To avoid this the number of arms is increased. Provision is also made to meet special circumstances, to add arms which vary in length, which may form part of the anode or not.

The proportion of water to ore in the sludge is a condition that also affects this department of the treatment, and it is found that between equal weights and proportions the best results are obtained when the water weighs three-fifths of the ore.

* Paper read before the Institution of Electrical Engineers, London.

* Similar means to some of those I have mentioned for doing the same work have been patented by De Neufville, September, 1895; Recker, August, 1897; but, with the exception of the combination of very minor details, these present no features of originality.

As regards the current, the potential should be capable of being governed between 5 and 14 volts, and this must be done by resistances fixed in the circuit of each vat or group of vats. For instance, when using vats of 9 feet interior diameter, each capable of treating 2½ tons of ore in two shifts—total 5 tons—in a day of 24 hours, should a plant to treat 200 tons of ore a day be worked, 40 vats will be required, and these would probably be governed in eight groups of five vats in a group. The quantity is regulated by the resistance in that part of the external circuit which lies between the electrodes. Provision is made for a minimum quantity of 1½ amperes per square foot, being half the sum of the cathode and anode together in square feet; thus, if that area is equal to 52 square feet, the current should not be less, and not much more than 39 amperes.

The inventors claim the use of several other forms of apparatus to effect the same objects, the details of which are more or less original, and are wholly original as forming parts of combinations; and they also describe conditions of variations of temperature during the progress of the treatment, as well as the addition of specific oxidizing agents and compounds and organic acids—all of which are matters appertaining to the discoveries they have made in experimentally treating samples on a working scale of ores from over 200 mines.

In an investigation of the electro-chemistry of the process I shall confine myself to the simplest (or circular) form of apparatus.

But before doing so it is well to remind any mining engineers who may be present that the degree of fineness of the pulverization employed is obviously a varying factor in considering this part of my subject, both as regards the chemical and electrical, and their combined effects, especially when dealing with refractory ores.

The advocates of treatment by simple leaching with chemical solutions dislike fine crushing, say, finer than will pass a mesh of 20 to 30 to the lineal inch, because it encourages the formation of "slimes" in the presence of which systems of treatment that act by means of percolation become less effective.

In those systems of treatment in which extreme fineness is not detrimental—rather otherwise—crushing so that the powdered ore will pass a mesh of 80 to 100 to the lineal inch is easily practicable, and makers of milling machinery have no hesitation in facing the problem.

Even then the way in which the work is done depends on the nature of the ore and the means employed. For instance, with some kinds of gangue, and of milling machinery, the particles in which the precious metal is intimately attached to a baser metal—say iron pyrites—instead of the result rendering them more pervious to chemicals, they may be found to be pressed out in solid, rounded and smooth atoms, and in the worst form for separation and subsequent stages of the process.

These conditions would govern the net results, subject to the cost of fine crushing.

To enable you to follow the course of what happens in the treatment tank, the process will be divided into more than one stage, although the actual order in which they follow one another, and the time occupied by each, may vary with the ore under treatment, and it is not always the case that it is worth while to separate them even for a short time.

During the whole time of treatment, "agitation" as distinguished from "percolation" or "circulation," is going on. The stages may be with or without the accompaniment of an electric current during portions of the time, but in any case the current is used during more or less of the time.

The liquid may contain sodium chloride (Na Cl) or potassium cyanide (KCN) alone, or both; but as the sodium chloride is directly and in the first instance used to "reduce the resistance" or "increase the conductivity" of the solution, there is no stage during which—except for the purpose of mixing—it is used alone, without being accompanied by the current.

The expressions I have used—namely, "reduction of resistance" and "increase of conductivity"—are useful because they are easily understood; but, be it remembered, they are not correct as applied to the solvent, i. e., water. Indeed, these descriptions of the effect of the mixture of sodium chloride in a solution, and then placing that solution between an anode and a cathode is scientifically inaccurate. What happens to the sodium chloride in solution in water is, that it is disintegrated and re-formed, and thus it becomes the intermediary by which, at the instant that chlorine gas and sodium are set free the current is enabled to "communicate" between the electrodes.

During the time of electrolysis, when the liquid contains only sodium chloride (Na Cl), the primary decomposition will be sodium (Na) and chlorine (Cl). In practice the quantity by weight of Na Cl may be between 0.2 and 1 per cent. of the weight of the ore in the sludge, but this depends upon the nature of the gangue. In any case, the presence and addition as required of sodium chloride is a regulator of the electrical resistance of the solution which at any given moment is situated between the cathode and the anode, and as the resistance in the conductors counts for very little, it practically affords means of governing the current in the external circuit of the electrical generator or dynamo. Of the several compounds which might be used for the same purpose, common salt is doubtless much the cheapest.

Now to consider the action of these products of electrolysis. As the sodium is liberated, in contact with the mercury cathode, a small proportion will no doubt be dissolved in the mercury as an amalgam. If the current ceases, this is converted into sodium hydrate (Na HO), with liberation of hydrogen.

But the greater part of the sodium liberated will react at once with the water in the solution, giving Na H O and H, the former to be used as described further on. Most of the chlorine liberated will at first be dissolved in the solution, but, as the liberation will take place at the surface of the anode, a small quantity may be used up in attacking the metal of which the anode is made.

While this is going on, the liquid immediately in contact with the cathode will become rich in sodium hydrate (Na H O), and the agitation will cause it to come in contact with the chlorine liberated at the anode, with some of it to re-form sodium chloride (Na Cl), and with another portion sodium hypochlorite (Na Cl O) and water (H_2).

$$2\,Na\,H\,O + Cl_2 = Na\,Cl + Na\,Cl\,O + H_2\,O.$$

At a higher temperature, say 130° Fahr., the Na Cl O would become sodium chlorate, according to the following equation:

$$3\,Na\,Cl\,O = Na\,Cl\,O_3 + 2\,Na\,Cl.$$

This formation of hypochlorite in solution will, subject to the adverse conditions caused by agitation, be directly in proportion to the quantity of Na Cl used to regulate the resistance, and with the relations of the areas of the anode and cathode respectively.

But this formation of sodium hypochlorite will be limited by the extent to which the sodium hydrate above referred to, when it is liberated at the cathode, rises to lay hold of the chlorine which is rich around the anode. This we may regard as taking place in spite of the agitation of the stirrers, which probably tends to cause temporarily a rapid diffusion of the chlorine and sodium hydrate separately in the solution, although eventually they must come together.

Although, when not in excess, it is a useful oxidizer, this formation of sodium hypochlorite has little advantage; and when potassium cyanide is added to the solution, it is, when in excess, even when alkaline, likely to oxidize some of it into potassium cyanate—a decided disadvantage, as it is a salt which is easily decomposed, and much less useful.

Let us now consider what may be effected by the chlorine liberated, but not engaged, as above described. In the first place, one might expect the nascent chlorine to attack some of the baser metallic ores present in a finely divided state. For instance, sulphides, selenides, arsenides, etc., often attached to particles of gold or silver, would be so attacked; the chlorine uniting with the metallic base iron (Fe) or copper (Cu), and the (S) sulphur (Se) selenium, or (As) arsenic being oxidized by the combined action of the chlorine and sodium hypochlorite above alluded to, into sulphuric, selenic or arsenic acids.

These changes would be marked by the formation of sodium sulphate, sodium selenate, etc., and the consequent formation of free acids, including hydrochloric acid. The reaction in this process may be represented in two stages, as follows:

$$Fe\,S + Cl_2 = Fe\,Cl_2 + S,$$

or $Fe\,S_2 + Cl_2 = Fe\,Cl_2 + S_2$ (iron pyrite), and

$$S + Na\,Cl\,O + 4\,Cl + 3\,H_2\,O = Na\,H\,S\,O_4 + 5\,H\,Cl.$$

This probably represents what actually is the cause of disintegration of some of the metallic compounds which are present in refractory ores, as the chlorine attacks these first in preference to the gold. At the same time, it is no doubt the case that, as the process continues, some of the gold is brought into solution by the chlorine diffused through it, as chloride of gold ($Au\,Cl_3$), which is readily deposited by electrolysis on the mercury.

We all know that the solution of gold by chlorine is in common use, but I think that in the example given it is effected under novel conditions, the chlorine being added electrolytically instead of mechanically.

During the first two or three hours of treatment by agitation with the electric current, there is no doubt that the free gold which is not dissolved will be precipitated, the heavy particles at a very early stage of the process.

In all such mixtures there is also more or less of what is called "float" gold, which in the processes using "percolation," and even "circulation," is lost in the "slimes." These particles, if they escape solution, will be so well mixed up in, and diffused through, the solution by agitation, that they should all in their turn be brought into close neighborhood of the mercury surface of the cathode.

The advantage of mechanically adding small quantities of sodium to mercury employed in gold extraction to assist amalgamation has long been recognized, but in this case the sodium so used is provided electrolytically. There is little doubt that the heavier particles of gold and silver which reach the bottom by subsidence will, owing to the surface being strongly polarized both by the current and by the slight amount of sodium amalgam formed by the current, be more readily amalgamated, and the same conditions also will promote the seizure by the mercury of the minute particles of float gold and silver when they approach its surface. The reason for this is probably not merely that it is thereby "kept clean"—i.e., free from oxide in the well-known sense—but that the difference of electrical potential set up between the mercury and the liquid alters the surface tension at the liquid junction, and helps the metallic particles to come in actual contact with the mercury. This is, I believe, a new way of defining what occurs when what is called "prevention of flouring," and the establishment of metallic contact with the mercury, takes place.

The presence of the excess of an acid such as hydrochloric acid has to be provided for by the addition say, of lime, to make the solution neutral; but this will not get rid of any excess of hypochlorite, previously mentioned, if present.

Lime, to remove free chlorine, will not be added until any metals in the solution, such as copper sulphides or arsenides have been formed into electrolyzed salts through conversion into chlorides. These,

which cause waste of cyanide of potassium, would to a certain extent go into solution, and by electrolytic action become deposited in the mercury and their values saved.

It will be understood, therefore, that all this preliminary work not only amalgamates a large proportion of the free gold and silver, but also prepares for the more effective action of potassium cyanide, both as a solvent and as an auxiliary in producing the condition of increased conductivity in the solution.

Thus, everything that chlorine can do to help the disintegration of the metallic ores which are found accompanying gold facilitates the action of potassium cyanide when it is added. This preliminary disintegration would be helped, not hindred, by temporary increased acidity of the liquid, when bodies like sulphides are oxidized at the expense of the chlorine; showing that the best time for neutralizing the solution is at the end of this preliminary stage, and just before the potassium cyanide is introduced.

In all this preliminary stage it will be seen that the eventual economy of potassium cyanide (or other solvent) should be aimed at, because, although with "percolation" processes the "leaching" can be effected with even half a pound of it, as much as two pounds of it to the ton of ore under treatment may be here required. Obviously, the greater part of it is wasted, as in treating a low grade ore containing, say 15 grammes of gold and say 30 grammes of silver, 60 per cent. of the gold and 40 per cent. of the silver may be separated and amalgamated in the first two or three hours, and before the potassium cyanide is added. Clearly it does not require 2 lbs. to treat 6 grammes of gold and 18 grammes of silver, even if all the values that remain in the sludge could be dissolved.

The addition of potassium cyanide (KCN) to an ordinary agitating vat causes the solution of some of the finely divided gold; and a further solution will ensue when, by the passage of an electric current, a decomposition yielding free cyanogen at the anode and caustic potash and hydrogen at the cathode will ensue. So far the reactions are common to all arrangements which combine agitation with electro-cyanide processes. They are, with dissolved oxygen alone available—

$$4\,KCN + Au_2 + H_2O + O = 2\,KAu\,(Cn)_2 + 2KHO;$$

with nascent cyanogen—

$$KCN + Au + CN = K\,Au\,(CN)_2.$$

The addition of potassium cyanide in excess in the Pelatan-Clerici process has been doubtless due to the necessity of allowing for the oxidization of it by any excess of hypochlorite previously mentioned.

$$Na\,Cl\,O + KCN = Na\,Cl + KCNO.$$

It is also desirable to have some cyanide to spare, because the cyanogen ($C_2\,N_2$) formed at the anode and dissolved in the solution will readily unite with the minutest and lightest particles of gold, to form with some of the said excess of it the double cyanide of gold [$Au\,K\,(CN)_2$], which is a salt that is easily soluble and readily electrolyzed.

These conditions point to the advantage of getting rid of any excess of hypochlorite and of acidity by neutralization before the cyanide (KCN) is added; also avoiding excessive oxidization of it, when if an insufficiency were to ensue and tests were neglected it is possible that Au CN might be formed and remain insoluble, and hence escape electrolysis and pass away in the tailings.

There is an advantage also in the simultaneous electrolysis of both sodium chloride and potassium cyanide, though the duty of the former is principally to facilitate the conductivity of the electrolyte. Chlorine and cyanogen are both yielded at the anode and would probably lead to the production of cyanogen chloride, which (in common with cyanogen bromide) would be in the presence of potassium cyanide as effective in attacking gold, if not more so, as cyanogen itself. The difference between this and what is known as the Sulman-Teed process is, that in it cyanogen chloride (or bromide) is added mechanically to a solution containing potassium cyanide and gold or silver ore, whereas in this process the conditions to effect a corresponding reaction are produced electrolytically.

To Mr. E. F. Herroun of King's College I owe every thanks for assisting me to prepare the above investigation of some of the features of the process.

POWER NECESSARY TO KEEP TRAMWAY CARS IN MOTION.*

This subject is of course a very simple one, but it has been suggested to us that it might be a convenience to readers to give in a compact form for purposes of reference the method by which the horse-power is arrived at. We shall take the two separate cases of a car on the level and a car climbing a grade. In each case the horse-power means the product of the speed and the actual pull on the car as with horse or cable traction, or its equivalent in rotating power applied to the axle as in the case of a steam or electric car. It is the actual useful power which must remain after all losses in generation, transmission and transformation are deducted. A rule for calculation can probably be better remembered and more easily applied if, in addition to giving the rule in words, it can also be reduced to a simple formula which can be applied to the solution of every case. The foundation of the rule is the tractive effort per ton needed to keep a car moving at uniform speed on a level straight track. Experiment shows that on the average this pull is equal to about 30 lb. per ton. If the rails are exceptionally clean, say when heavy rain is falling and the grooves are completely void of dirt, the pull may fall to considerably under 20 lb. per ton, approximating to the 10 lb. or 12 lb. per ton necessary on a level steam railway. On the other hand, with very dirty clogged rails the pull may have to be more than 30 lb. Taking it at the average, the whole force resisting motion is 30 lb., multiplied by the weight of the car and passengers in tons. The speed of the car in miles per hour must be worked out in feet per minute, and manifestly the product of the total pull in pounds multiplied by the number of feet traveled per minute will give the number of foot-pounds per minute expended. Divide this by 33,000 (the number of foot pounds per minute equal to one mechanical horse-power), and we have the horse-power exerted. Accordingly to focus the rule we may write:

$$\text{HP.} = \frac{T \times W \times S}{33{,}000},$$

where T represents tractive force per ton, W the weight of the car and passengers in tons, and S the speed in feet per minute. To apply the equation to a given case it is required to find the power necessary to drive an electric car, weighing with passengers eight tons, along the level at a speed of eight miles an hour, the tractive resistance being 30 lbs. per ton. The speed in feet per minute is here:

$$\frac{5{,}280 \times 8}{60} = 704.$$

We accordingly have:

$$\text{HP.} = \frac{30 \times 8 \times 704}{33{,}000} = \frac{168{,}960 \text{ ft. pounds}}{33{,}000} =$$

5 horse-power fully.

To calculate the total power consumed when the car is mounting a grade we obtain the power as before for traveling on the level, then the power necessary to do the work against gravity, and add the two results together. When the steepness of the incline is given, we get the vertical rise of the car per minute by dividing the number of feet traveled per minute by the number of feet in which a vertical rise of one foot occurs—say 30 feet when the grade is 1 in 30, 20 feet when it is 1 in 20, and so on. Then the weight of the car and passengers in pounds multiplied by the number of feet of vertical rise per minute gives the number of foot-pounds per minute against gravity. If S is the speed of the car in feet per minute, F the distance in feet in which a vertical rise of 1 foot occurs, and W′ is the weight in pounds of the car and passengers, then

$$\text{Work in ft. pounds done against gravity} = \frac{S}{F} \times W'.$$

We can now apply both elements to a case. If a car weighing with passengers 8 tons is traveling up an incline of 1 in 16 at 6 miles an hour, the tractive resistance on the level being 30 lbs. per ton, what horse-power is being consumed? First, get the power for the level. The equation for this is:

$$\text{HP.} = \frac{T \times W \times S}{33{,}000}$$

$$\text{HP.} = \frac{30 \times 8 \times 528}{33{,}000} = \frac{126{,}720}{33{,}000}$$

To save an extra division we may here leave the 126,720 foot-pounds as it stands. Now for the work done against gravity, represented by

$$\frac{S}{F} \times W'.$$

This is equal to

$$\frac{528}{16} \times 8 \times 2{,}240 = 33 \times 17{,}920 = 581{,}360 \text{ ft.-lbs.}$$

It will be seen from the above that the vertical rise per minute is 33 feet, and the weight of the car is 17,920 lbs. We now add the work done on the level to that done against gravity and divide by 33,000:

$$\frac{126{,}720 + 581{,}360}{33{,}000} = \frac{708{,}080}{33{,}000} = 21\tfrac{1}{2} \text{ HP. (nearly).}$$

It seems really absurd to use something like an algebraic equation for such a simple matter when one is working out a case with a rule before him, but it is put in that way here as an aid to memory. Most people will agree that if an equation is few in its terms it sticks in the mind when the signification attached to each letter is known.

The above results have no application to the question of the power necessary to start a car from a position of rest. The exact power can hardly be stated for any particular case, as it is variable, depending a great deal on the slightest of grades at th point covered by the wheels at the moment of starting, and on the presence even of small obstructions on the rails immediately in front of the point of contact of wheel and rail. It is not far wrong, in the case of a start on level, or approximately level, track to take the power necessary at three or four times that required for maintaining uniform speed. This great power however is only needed for a moment, and rapidly falls off as speed is gained.

The rule for ascertaining the power used in climbing inclines applies (when calculating the total power expended at the cars on a tramway) equally to all forms of haulage except cable traction. In the latter case all the cars on the line are attached to the cable, and the number descending a hill at any given time may be taken on the average to equal the number ascending. Hence the gravity of the descending cars helps the ascending ones, and so saves power at the engine-house. It is not meant that the car going up needs less power than if another method of haulage were adopted, but that part of the total power it absorbs is supplied by the gravity of the car coming down hill on the other line. The whole of a cable tramway over a hilly route thus requires little or no more power at the engine-house than if the route were level. This is a unique advantage of cable traction for hilly routes. When horse, steam, electric or other power is used the gravitating power of the cars down hill is dissipated in the brakes, while with the cable system it is conveyed to the cable to help to pull the ascending cars up hill. Readers interested in this branch of the subject can easily calculate for a given hilly route the enormous power

* From *Railway World*, London.

(allowance being made for the mechanical efficiency of the system) which must be provided for each car when any form of traction other than cable is employed. It is of course understood that the advantage from this point of view of cable haulage does not become fully apparent unless the service of cars is a frequent one. On nearly all cable lines, however, the last condition is fulfilled.

COMMERCIAL FORMS OF ELECTRICAL RESISTANCES USED FOR LIGHTING AND POWER PURPOSES.*

BY L. B. ATKINSON.

(*Concluded from page 102.*)

It may be well now to describe and illustrate forms of resistance embodying the arrangements already set forth.

Fig. 1 shows the old fashion wooden resistance box, with wire coils. Figs. 2 and 3 show the original fire-proof resistance designed by the author in 1886. Figs. 4, 5 and 6 show other forms of resistances using coiled wires. In all these the wires are carried in an iron frame, either on slate strips or on porcelain insulators, and a multiple switch, with connections to the wires, enables more or less of the resistance to be put in circuit.

Fig. 7 shows a form of carbon resistance.

These resistances are useful for experimental work, but they will not carry or dissipate any large amount of power.

In Fig. 7 the resistance is shown in an iron frame screwed up from one end, such a form however being only useful for low resistances and large currents,

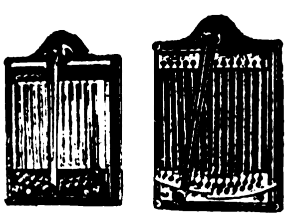

FIG. 4.

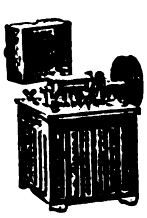

FIG. 5.

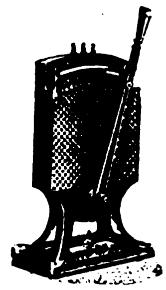

FIG. 6.

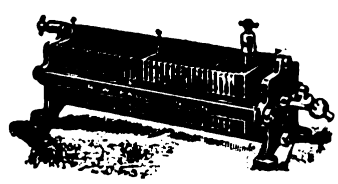

FIG. 7.

the specific resistance of carbon being too low except in this case.

Figs. 8 and 9 show various forms of resistance designs by the writer, in which the new material "relugite" is used.

In Figs. 8 and 9 the top and bottom plates are of iron, enamelled on the inside; there is a central bolt

FIG. 8.

FIG. 9.

also insulated by enamel, and a pile of plates alternately of the material and of metal lies between these plates, and the pressure is adjusted in Fig. 8 by a handwheel and in Fig. 9 by a nut.

Figs. 10, 11, 12 and 13 show various forms of liquid resistances; Fig. 10 is a form used for laboratory purposes, and with a dilute solution of zinc sulphate may carry as much as 2,000 volts between the electrodes.

Fig. 11 shows a form used for motor starting; the segment forming one electrode is shown partly immersed, the outer casing, which is of iron, forming the second electrode.

When completely immersed, a contact on the segment support short circuits the resistance entirely.

* Paper read before the Northern Society of Electrical Engineers at Manchester, Eng.

Fig. 12 shows a form of liquid resistance which the writer has used, the current entering at the bottom of one tube and leaving at the bottom of the next tube, a wire fork or bridge being raised or lowered in the tubes.

A curious phenomenon occurs with such an arrangement, the complete explanation of which the writer is unable to give, viz., that using lead plates at the bottom of the tubes and a copper or iron

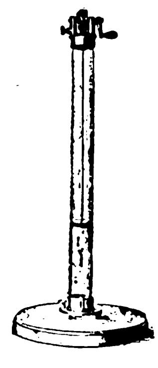

FIG. 10.

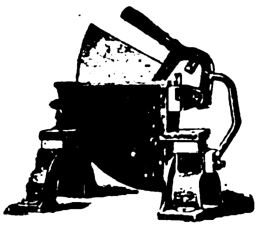

FIG. 11.

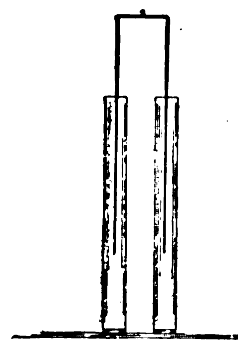

FIG. 12.

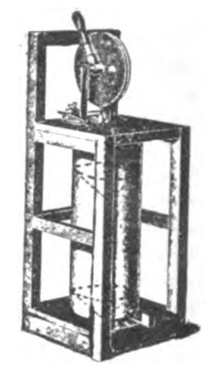

FIG. 13.

bridging piece, the resistance and heating effect is not equally divided between the tubes but is largely concentrated in one of them.

Fig. 13 shows a form of liquid resistance used for lowering lights for theatrical purposes, and consists in an earthen pot or jar, at the bottom of which is a lead cone, another lead cone being raised or lowered in the jar. These are shown by dotted lines.

Fig. 14 shows a form of resistance generally used for motor starting only, as the cooling surface is small, in which the wires are embedded in asbestos, enamel or cement; this will be referred to again.

ADAPTATION OF RESISTANCES FOR SPECIAL PURPOSES.

Resistances for Regulating Dynamo and Motor Shunts.—Almost any of the forms which have been described are suitable for this purpose. As to capacity, the maximum amount of power to be dissipated is reached when the resistance is equal to the resistance of the shunt, and when the current comes down to half its original value.

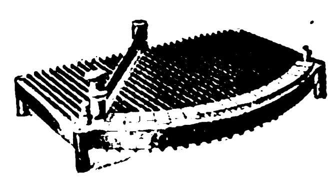

FIG. 14.

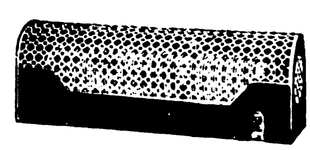

FIG. 15.

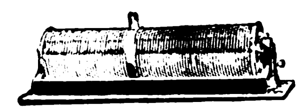

FIG. 16.

Resistances working by compression, and therefore

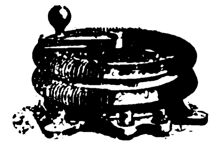

FIG. 17.

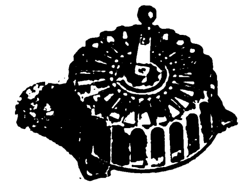

FIG. 18.

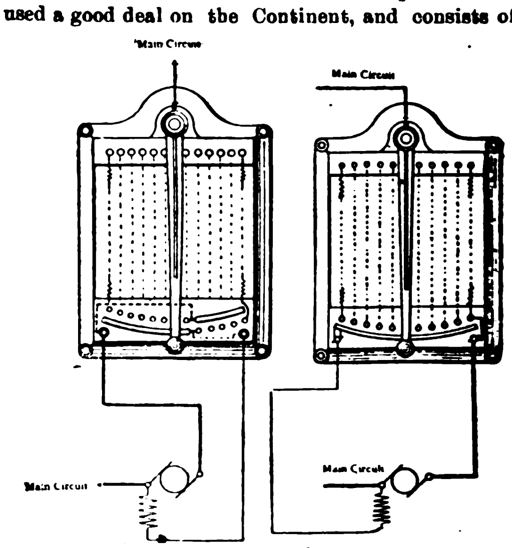
giving a perfectly steady graduation between maximum and minimum, have the advantage of allowing the EMF. to be regulated very exactly, an advantage where dynamos are being run in parallel.

Arc Lamp Resistances.—These form an important class, as very large numbers of them are used.

Fig. 16 shows the usual form, consisting of a porcelain cylinder, having a spiral upon it, in which is wound a german-silver wire. The resistance is regulated by a movable clamp placing more or less of the wires in circuit.

Fig. 15 shows the same arrangement, with a perforated cover to allow of ventilation.

Figs. 17 and 18 (which is the same resistance with a cover on it) shows a form of arc lamp resistance used a good deal on the Continent, and consists of



Starting resistance with shunt regulation. Starting resistance without shunt regulation.

FIG. 19.

two earthenware disks, having a groove on the periphery, round which a wire coil is stretched.

The adjustment is made by a movable contact sliding over one of the coils.

Resistances for Lowering Lamps.—These are mostly used for stage effects, and if made with switches should have a large number of contacts to make the graduation imperceptible, or liquid resistances or resistances worked by pressure variation should be used.

Owing to the peculiar nature of the fire risks in the theater, special care should be taken that the rise of temperature should be small.

In the case of resistances designed by the writer for the Drury Lane Theater, the specification was that the resistances should not rise more than 80° F. above that of the atmosphere.

Resistances for Meter and Instrument Testing.—For this purpose resistances with sliding wire, or liquid resistances, have been generally used, enabling the current to be kept at an *exact* value. A "relugite" pressure resistance is now being adopted for this purpose. It has the additional advantage with al-

ternate currents that the resistance being inductionless no errors are introduced.

Motor Starting Resistances.—It has frequently been a subject of complaint that the resistances for starting both continuous current and multiphase motors, particularly for small powers, cost almost as much as the motor itself. This has been largely due to want of standard designs specially suited for the purpose.

In general the resistance is not required for more than say one minute, but should be capable of carrying the full load of the motor for that time. Some forms recently introduced will only carry the load for 20 seconds; this is not safe.

Fig. 14 shows a form of resistance specially adapted for this purpose.

Fig. 5 shows a form in which the resistance is gradually removed by the motion of the motor after starting.

For the purpose of regulating the speed of motors the resistances must be made larger, and must be capable of carrying a load depending on the range of regulation, but if this is a wide one practically the full load of the motor must be provided for. The simplest way of regulating the speed of a shunt motor is shown in the right hand diagram of Fig. 19 where a resistance is placed in circuit with the armature of the motor, the full line pressure always being on the shunt coil. The left-hand diagram of Fig. 19 shows a modified arrangement, in which part of the speed regulation is effected by varying the strength of the current in the magnet coils. In this case the method of working is to have, in the first instance, the full line pressure on the magnet coils and resistance in the armature circuit. The resistance is gradually taken out of the armature circuit, and resistance is then inserted in the magnet circuit, thus weakening the field and allowing the speed to rise.

If this form of regulation is to be adopted the magnet windings should be specially arranged for apparatus to have a low resistance, so that the motor is considerably over-excited at starting.

Figs. 11 and 13 show resistances also well adapted for motor starting, and pressure resistances filled with either carbon or "relugite" are also used for this purpose.

In order to avoid the possibility of a motor being switched into circuit rapidly, it is preferable to fit such resistances with a screw motion, but if this is done, arrangements must be made by a separate switch or otherwise, so that the circuit can be broken instantaneously in the case of accident or emergency.

An important point in connection with regulating resistances, particularly where the variation in resistance from point to point is considerable, is the question of the switch contacts, as considerable sparking occurs on the contacts which from this cause becomes dirty or roughened, and causes considerable trouble.

In a form of switch pillar for starting and regulating speed of motors designed by Messrs. Royce independent quick break contacts are fitted at each resistance point, and the final break is effected by a carbon contact. In a form designed by Pochin, the switch arm itself carries a small wiper which takes the spark and may be renewed as required.

In the case of pressure resistances these precautions are unnecessary, and even in the case of resistances with multiple contacts and filled with "relugite" material, owing to the fact that such resistances are inductionless, the spark on the contacts is practically eliminated.

CONCLUSION.

In conclusion, the writer desires to point out the advances which have taken place in the last few years in the design and manufacture of resistances, owing largely to the increased demand, and therefore to the specialization which this has allowed, and hopes that the notes contained in the foregoing paper will prove of interest to the members of the Northern Society of Electrical Engineers, who have doubtless had considerable experience not only of the merits, but of the disadvantages to which this class of apparatus is liable.

From a manufacturer's point of view, it is greatly to be desired that engineers designing plants will endeavor to avail themselves of manufacturers' existing patterns and standards rather than to specify for particular arrangements, as it is only in this way that the cost of accessories of the electric light and power plants can be brought to a point which will have the effect of greatly stimulating the use of electrical appliances in many cases where at present the admitted advantages do not outweigh the expenditure necessary.

MINES RUN BY ELECTRICITY.

The Canon City-Cripple Creek Power Transmission Plant in Operation.

The following letter from a correspondent of ELECTRICITY in Canon City, Col., gives an interesting account of an event of more than ordinary importance to the mining interests of Colorado:

At noon on the 17th inst. Governor Alva Adams pressed the button which was the means of putting in motion the massive machinery of the Colorado Electric Power Company at Canon City, the electrical current being transmitted to motors at the Cripple Creek gold mines, 24 miles distant, where arrangements have been carried out to have them take the place of the usual steam power equipment that has heretofore been in use. This means the successful accomplishment of another big undertaking which adds to Cripple Creek's greatness as the foremost gold-producing camp in the United States and at the same time records another instance where electricity was considered as the model power for mining purposes by a community of practical men.

The occasion was witnessed by 400 prominent mine-owners from Colorado and other parts of the country. After a thorough inspection of the plant had been made, the visiting mining men were dined and Governor Adams delivered an address on what the new enterprise meant for Cripple Creek in particular and the State of Colorado in general, which completed the installation of the new plant.

In brief, the scheme is to generate electricity at Canon City, which is in the midst of extensive coal fields, and transmit the power to Cripple Creek, where coal, which is a prime necessity in the running of the mines, sells at a high figure. This will enable mines to be operated at a profit that have heretofore been close to losing properties, and at the same time effect a very great saving in running expenses with the large producers. It promises to be a very important point in the future development of the camp.

The plant is one of the largest and best equipped electric power concerns in the West. The equipment consists of three Hamilton-Corliss engines, with a combined strength of 9,000 HP., direct connected to three Westinghouse three-phase generators of 2,100 kilowatts capacity, wound for 500 volts, making three separate generating units, one of which will always be kept idle as a reserve in case of an emergency. For exciting the fields of the main dynamos there are two "Kodak" exciter outfits, each of which is capable of exciting all three of the main dynamos; one of these exciter outfits will always be kept in reserve for emergencies.

The engines are supplied from a battery of Heine safety tube boilers and the exhaust steam is taken care of in a surface condenser. The air and circulating pumps and feed pumps are all of the Snow make.

There have been installed at the main station four transformers that step up from 500 to 20,000 volts, at which pressure the current is delivered to the transmission line. The first sub-station is near Victor, on the saddle between Battle Mountain and Bull Hill. The location of the second sub-station is on the saddle between Gold Hill and Globe Hill, near Cripple Creek. At each of the sub-stations the current steps down by means of transformers to 500 volts, at which pressure it is delivered to the motors in the mines.

In addition, lights are to be supplied from the same wires used to furnish power. One of the prominent features in the construction of this plant is the insuring of continuous service. The machinery and construction are of the very best, and ample reserve capacity is carried throughout. The construction of the transmission line is substantial, and particular pains have been taken to protect it from lightning troubles. In addition to the lightning arresters in the generating station at Canon City and in the sub-stations, lightning arresters have been installed at a number of points along the transmission line, the "Wurts" arrester being adopted throughout.

It should be added that in addition to the 24 miles of line between Canon City and Cripple Creek there is about six miles of line over the camp, which will make the total length of the system about thirty miles. The work of constructing this system was commenced last September, and after not quite 12 months everything is in readiness.

The entire line is patrolled by experienced line men who carry with them a telephone specially adapted for their work which they can connect with the main line at any point and send in word wherever they find a break. Western Union call boxes are stationed along the line, and through them the patrolman must report where he is every hour.

The main station of the Colorado Electric Power Company's plant is a substantial structure 140x106 feet, constructed of brick, stone and cement, with steel trusses and corrugated iron roofing, and allowance has been made so that the entire plant can be duplicated without the addition of another smoke stack or extra condensers.

This plant has cost an enormous sum of money, probably not less than $750,000. The company is made up of such capitalists as John D. Rockefeller, Andrew Carnegie, the Westinghouse Company, etc.

The transmission line was erected under the supervision of the Mountain Electric Company of Denver, for which they used a specially designed insulator gotten up by them. This company by careful and painstaking work has gained a reputation as being second to none in this section for transmission construction work. The generating apparatus was installed by the Westinghouse Company and the steam equipment was put in under the supervision of the Stearns-Rogers Company of Denver.

It has been carefully computed that there will be a saving of 30 per cent. in the operating expenses of the mines if electricity is used, in so far as the matter of hoisting the ore, running drills and doing whatever steam can do is concerned. Then again there can be no argument brought against the convenience. In the place of unwieldy steam boilers that are getting out of fix every now and then, a trim little motor, perhaps 3x5 feet, does the work. There is no dust, no grease, no lugging coal up the sides of mountains to the mines, and no breakdowns. But this last point suggests another—will there be no breakdowns? It has been gathered from statistics that the experience of the Fresno, Cal., plant is typical of all; in that instance during two years that the plant has been in operation there has been but three stops—two for five minutes and one for twenty minutes—in all thirty minutes.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

ANNUAL MEETING OF THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

The eighth annual meeting of the American Electro-Therapeutic Association will take place in Buffalo on the 13th, 14th and 15th of September. The business sessions of the Association will be held in the rooms of the Buffalo Society of Natural Sciences, Public Library building. The Buffalo *Commercial* contains the following interesting particulars of the approaching meeting:

An exhibition of electrical apparatus for diagnostic, therapeutic and radiographic work will be one of the interesting features of the Convention. A large number of entertainments will be provided by the local committee of arrangements, including tallyho drives about the city daily, a public reception on Tuesday evening (13th), an excursion down Niagara river and a reception at the Island Club, Grand Island, with a number of other receptions, visits to industries of interest, etc. Special hotel rates will be secured at Niagara Falls as well as in Buffalo for all attending the Convention.

A preliminary programme has been arranged for the Convention, embracing a large number of interesting topics. Time will be given to a series of ten-minute discussions on electro-therapy, of special interest to the general practitioner, including the following subjects: "Effect of Electricity on Tissue Metabolism," "Electro Diagnosis," "Diseases of the Nervous System," and other topics.

Among the papers promised for the Convention are some by the most noted writers on medical topics in this country, and several physicians of Europe who are acknowledged international authorities on their special subjects.

Dr. Apostoli of Paris, France, will present a paper entitled "Notes on New Applications of the Sinusoidal Currents in Electro-Therapeutics."

Dr. Gautier, also of Paris, will present several subjects before the Convention, as follows: "The Hydro-Electric Bath with Sinusoidal Current in Disease," "On the Value of Hot Air and Light Bath in Disease," "Two Years of Practice in Radio-Therapy," "Electro-Therapy in Gynecological Applications."

"Electricity in the Cure of Uterine Fibromyomata" will be the subject of a paper by Dr. Felice La Torre of Rome, Italy.

Dr. J. Inglis Parsons of London, Eng., will present a paper on "The Effect of High Tension Discharges upon Micro-Organisms."

A paper which will be heard with wide interest will be presented by Nikola Tesla, on "High Frequency Oscillator for Electro-Therapeutic Purposes."

Buffalo will be represented on the programme, Dr. William C. Krauss reading a paper on "Case of Lightning Stroke without Serious Consequences," and Dr. Lucien Howe, Buffalo's celebrated oculist, speaking on "The Method for Using Cataphoresis in Certain Forms of Conjunctival Inflammations."

Dr. John O. Doe of Rochester, N. Y., will read a paper on "The Uses of Electricity in Diseases of the Nose and Throat." J. J. Carty, E. E., of New York, will speak on "Some Suggestions on the Possibilities of Cataphoresis."

"The Electric Light Bath" will be the subject of a paper by Dr. J. H. Kellogg of Battle Creek, Mich. Dr. M. A. Cleaves of New York will treat on "Metallic Electrolysis, with Laboratory Experiments," also on "Electrical Treatment of Inflammatory Exudates."

"Electricity in Gynecology" will be the subject of a paper by Dr. W. J. Herdman of Ann Arbor. Dr. A. D. Rockwell of New York will speak on "Diagnostic and Therapeutic Relation of Electricity to Diseases of the Central Nervous System."

Another paper from a Buffalo man will be by Dr. Grover W. Wende, who will speak on "Electricity in Acne Vulgaris and Acne Rosacrae."

"Cataphoric Action of the Galvanic Current" will be the subject of a paper by Dr. Caleb Brown of Sac City, Ia.

R. G. Brown, E. E., of Brooklyn, will present two subjects before the Convention, "New Electric Light for Diagnostic Purposes," and "Surface Electrodes, How They Should be Made; Connector Cords, How They Should be Made and Insulated."

Dr. Robert Newman of New York will speak on "Electricity in Deafness and Strictures of the Eustachian Tube." Dr. R. J. Nunn of Savannah, Ga., will speak on "Treatment of the Uterine Fibroids by Small Currents Administered Percutaneously."

"Treatment of Certain Muscular Affections by Means of Electricity" will be the subject of a paper by Dr. William F. Robinson of Albany. "True Status of Electricity and Allied Remedies in Treatment of Strictures and Prostatis" will be dealt with by Dr. G. W. Overall of Memphis, Tenn.

Dr. W. S. Watson of Fishkill-on-Hudson, N. Y., will speak on "Electricity and Medical Institutions." Dr. W. H. White of Boston, Mass., will present a paper on "Static Electricity in Nervous Diseases." Dr. H. S. Jewett of Dayton, O., has for his subject "The Misuse or Abuse of Electricity as a Therapeutic Agent." Dr. W. Schepp grell of New Orleans, La., will speak on "Electricity in Diagnoses of Disease of the Ear." Dr. W. H Harris of Toronto will present a paper on "X Ray Burns." Dr. F. B. Bishop of Washington, D. C., will speak on "High Tension Current in Neuritis."

All members of the medical and electrical professions are invited to the meetings of the Association.

The exhibition of apparatus, etc., will be held in the Public Library Building, and this will also be open to the public.

The present officers of the Association are as follows:

President—Dr. Charles R. Dickson of Toronto.

First Vice-President—Dr. Frederick Schavoir of Stamford, Conn.

Second Vice-President—Dr. Caleb Brown of Sac City, Ia.

Secretary—Dr. John Gerin of Auburn, N. Y.

Treasurer—Dr. Richard J. Nunn of Savannah, Ga.

Executive Council—Dr. Robert Newman of New York, Dr. G. Betton Massey of Philadelphia, Dr. William J. Morton of New York, Dr. William J. Herdman of Ann Arbor, Dr. William T. Bishop of Harrisburg.

Committee on Arrangements at Buffalo—Dr. Ernest Wende, chairman; Dr. W. W. Potter, printing; Newcomb Carlton, E. E., exhibits; Dr. Roswell Park, Dr. Herman E. Hayd, Dr. Henry R. Hopkins and Charles R. Huntley.

Ohio Electric Light Association.

The fourth Annual Convention of the Ohio Electric Light Association was held at Sandusky on the 19th and 20th inst. Fifty delegates were in attendance. Several papers were read and discussed and much interest was shown in the proceedings. On the 20th the members enjoyed a trip to Put-in-Bay as guests of the Sandusky Gas & Electric Company. Officers for the ensuing year were elected as follows:

President—Emil G. Schmidt, Sandusky.

Vice-president—B. P. Holmes, Youngstown.

Secretary-treasurer—Samuel Scovil, Cleveland.

Executive Committee—H. K. Wood, Piqua; B. P. Foster, Norwalk; George Matt, Lancaster; E. H. McKnight, Middletown; S. Griffin, Lorain.

The next Annual Convention will be held at Cleveland upon dates to be fixed by the Executive Committee.

LEGAL NOTES.

The Grand Rapids *Herald* states that Judge Severens has rendered a decision in the Lowell Water & Light Company case granting the application for a receiver. Some time ago the company placed its business in the hands of the Michigan Trust Company, which was against the wishes of the creditors, and they commenced suit to force the appointment of a receiver and have been successful.

On the 24th inst. Judge Lacombe issued preliminary injunctions restraining the Nassau Electric Railroad of Brooklyn, N. Y., from the further use of electric controllers made by the Steel Motor Company, and against the Walker Company enjoining its manufacture of the several types of car controllers manufactured by it. The operation of this injunction is suspended until the next session of the Court of Appeals, to give the defendants an opportunity for appeal.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING PLANTS.

Albany, N. Y.—The cost of lighting the Capitol under the existing contract with the Municipal Gas Company is $42,000 a year for electric lights and $14,700 a year for gas. There are 10,600 incandescent lights in the building, 56 arc lights on the grounds, and one of the elevators is run by electric power. With this great number of lights the service is not entirely satisfactory, and changes are contemplated which may result in the installation of an independent plant.

Carthage, Mo.—At an election held here on the 16th, the citizens expressed themselves as opposed to letting out any more contracts for city lighting to private corporations. The vote stood 244 for to 311 against.

Centreton, N. J.—The Parvin Mills, near here, have been sold to Philadelphia capitalists for $10,000. It is understood that an electric light plant will be placed there to light the surrounding country.

Covington, Ga.—A contract was made by the city with an electric light company in March last for lighting our streets with electric lights, but the company has since failed, and the council is now being urged to make an effort to secure another company to undertake the work.

East Greenville, Pa.—A movement has been on foot for several weeks to utilize the immense water power at the large dams of the J. C. Hancock Ice Co., at Green Lane, to operate an electric light plant. It is proposed to extend the plant to Sumneytown, Red Hill and the boroughs of Pennsburg and East Greenville.

Fergus Falls, Minn.—Superintendent Peterson of the electric light plant is preparing to put in new "leaders" which will give the plant a capacity of over 4,000 lights. The electric light system is owned by the city and is one of the finest in the Northwest.

Frankfort, Ky.—The State officials are taking steps to light the State buildings with electricity and will have a plant erected at the Penitentiary.

New York.—It is reported that the Metropolitan Street Railway Company has been quietly laying a large underground conduit in the excavations making for its underground trolley in Sixth and Eighth avenues, and that the conduit is to be used in a proposed electric light scheme under contemplation. The company has enormous power plants, and a slight addition to them, it is said, will be sufficient to furnish electric lights for a large part of the city.

Pittsburg, Pa.—The local papers state that the indications are that on the occasion of the triennial conclave of the Knights Templars, October 12, Pittsburg will give "the most unique, elaborate and wonderful electrical display that has ever been seen in the history of the electrical world."

San Francisco.—The Board of Supervisors has passed over the Mayor's veto the resolution awarding to the San Francisco Gas & Electric Company the contract for lighting the city for the next two years.

Silver City, N. M.—C. L. Slack is pushing operations on the electric light plant here and poles will be erected and wires strung in the principal streets in a few days.

Tallahassee, Fla.—The city council has passed a resolution "that steps should be taken immediately for the establishment by the city of an electric plant for lighting the streets and other public places of the city as will pay for such use."

Two Harbors, Minn.—The village recorder advertises for bids for $8,000 electric light bonds issued in denominations of $1,000, bearing interest of 6 per cent. per annum. Bids will be received until September 12.

Woodsfield, O.—The city council has decided to abandon the plan of lighting the streets by natural gas and is making investigations as to the cost of electric lighting.

STREET RAILWAYS.

Ann Arbor, Mich.—It is reported here that a corps of surveyors have been working east of Ypsilanti laying out a new electric road to parallel the Detroit, Ypsilanti & Ann Arbor line. It is said that the Michigan Central Railroad is promoting this new road, having found the competition of the electric road very severe.

Boston.—On the 19th inst., the first regular passenger car that ever passed over the entire trackage of the Boston subway accomplished the feat with complete success. The delegates to the annual convention of the Society for the Promotion of Engineering Education, then being held in the city, witnessed the test with the deepest interest and with apparent admiration.

Buffalo, N. Y.—The Buffalo, Kenmore & Tonawanda Electric Railway has been sold to Morris Cohn. The road is about five miles long and was built four years ago. The price was the amount of bonds held by Mr. Cohn, $63,147, and the amount of the claim of the assignees, $28,000, which the purchaser has agreed to satisfy.

Byron, Ill.—The voters of this place at a special election have declared in favor of granting the Rock River Electric Railway Company right of way through the streets.

Corsicana, Tex.—It is reported here that negotiations are now on foot that will result in the building of a street railroad in this city. It is said that the plans have about been perfected and that the line will be in operation before many months.

Elizabeth, N. J.—It is authoritatively stated that ex-Congressman John Kean, who bid $250,000 for the boulevard franchise, will at once transform his horse railroad in this city into an electric road and expects to complete the change by November 1.

Jasper, Ind.—Ferdinand, a nearby German town of 1,000 inhabitants, not incorporated, has an electric plant now under construction, and the preliminary steps have been taken to run an electric car line to Jasper.

Kansas City, Kan.—The city council has passed an ordinance providing for the changing of the Fifth street cable line into an electric system.

Lewiston, Me.—A correspondent of the "Journal" at York states that a prominent Boston & Maine official made the remark that within a year the Boston & Maine Railroad will operate by electricity the Portsmouth & Dover branch, the York Harbor road and a Portsmouth street line, with a joint power house on Nobles island in the Piscataqua river.

Northville, Mich.—A movement is on foot here to organize a stock company among business men to construct an electric railway from Northville to Novi, Walled Lake, Wixom, New Hudson, South Lyon, Salem and back to Northville. It is to be called the Northville Belt Line and will be in the nature of a circle. It will be about thirty miles in length. The farmers have agreed to do the grading free.

Nyack, N. Y.—The "Star" states that the Nyack Traction Company has sold the Nyack, South Nyack, Upper Nyack, Grand View, Piermont and Clarkstown trolley franchises to some Philadelphia capitalists, who intend to build the road. The franchises stipulate that the actual work of building the road must be commenced by November 18 or the franchises will become null and void.

Oakland, Cal.—It is announced, says the "Enquirer," "that at the next meeting of the city council a petition will be presented for permission to substitute electricity for the cable system now in use on the San Pablo avenue and Broadway line. Should the petition be granted it is believed it will be the forerunner of an entire change in the Southern Pacific Company's local passenger service. The ultimate plan is supposed to include the substitution of electricity for steam as a motive power on the entire system, including the Alameda and Berkeley local roads, the narrow gauge and the Seventh street line. A monster power house would be one of the necessary requisites."

Providence, R. I.—The Taunton & Providence Electric Railway line was formally opened on the 22d inst. by an excursion on the cars which was followed by a clambake provided by the managers.

Rochester, N. Y.—The Rochester & Sodus Bay Railway Company has completed its organization by the election of officers as follows: President, T. J. Nicholl; vice-presidents, first, J. C. Tone, second, Walter B. Duffy; treasurer, John H. Gregory; secretary, Charles Van Voorhis. The road will be about 42 miles long and is to be of the same general character as the electric roads running out of Buffalo, Cleveland, Detroit and other cities.

Sedalia, Mo.—The Citizens' National Bank of this city has sold the stock of the Sedalia Electric Railway, Light & Power Company and the Sedalia & Brown Electric Railway Company to Stewart & Co. of New York. The consideration was $400,000.

St. Louis.—The "Globe-Democrat" states that J. D. Houseman, Jr., the electric railroad promoter, who projected and built the "Houseman Air Line" from St. Louis to Meramec Highlands, is at the front with another big railroad project—the construction of a line from Robringville along the Telegraph county road to the Meramec river, and from there direct to Kimmswick, on the Iron Mountain road, about twenty miles from the St. Louis Court House.—The same paper says that the Illinois Central Railroad Company has announced officially the opening of an electric line between East St. Louis and Belleville. They will use the old St. Louis, Belleville and Southern road which will be equipped with the third rail system. The difficulty is the use of the road as an electric line and also as a railroad line; as this is the only outlet of the Crown coal lands, it will necessitate the running of freight trains over the new electric line.

Waupaca, Wis.—The Waupaca Electric Light & Railway Company has filed a trust deed to the Milwaukee Trust Company for $42,000, which gives assurance that the trolley line from Waupaca to Chain o' Lakes will be built as promised.

Watertown, N. Y.—William P. Casey, of Syracuse, has organized a company to build and operate a trolley line between Watertown and Sacket's Harbor. The amount of capital stock is $100,000. The directors for the first year are as follows: William P. Casey, James S. Luddington, James H. Kinney, H. D. Barto, Syracuse; Joseph Marrian, G. Harrison Smith, John E. Bergevin, Watertown; S. Harland Wetmore, Leyden; William H. Reese, Evans Mills. The principal office of the company is to be located in Watertown.

Wichita, Kan.—The mayor refused to accept the certificate of deposit for $10,000 tendered by W. Q. Church of New York as a guarantee for the faithful observance of the terms of the franchise granted him for a street railway in this city, and the franchise is held in abeyance. It now seems probable that the franchise will be annulled, the streets cleared of the present line and bonds voted for a new line to be constructed by the city at once.

MANUFACTURING, ETC.

Dublin, Ire.—The system of the Dublin United Tramways is being converted to electric traction, formerly having been operated by horse power. The first section completed is the Clontarf line, extending from Dublin through the suburbs, a total distance of about 6 miles. On this section the introduction of the trolley was signalized by a reduction of fares to a trifle more than half what they had been, notwithstanding which receipts increased 38 per cent. and working expenses were reduced from 71.76 per cent. with animal power to 47.69 per cent. under electric traction. The present population of Dublin numbers about 600,000.

Malaga, Spain.—A new company, the Nueva Sociedad de Electricidad Peeters, chiefly formed by German capital, is going to establish a permanent service of electric lighting in this city, considerably reducing prices which have ruled hitherto. The price per annum, paid in monthly instalments, is: 16-candle lamps, 38 pesetas; 10-candle lamps, 32 pesetas.

New York.—The "Journal of Commerce" states that on the 24th inst. a New street firm purchased, among other manufactured articles, $11,000 worth of electrical apparatus for shipment to Mexico, and also that electrical materials amounting to upwards of $10,000 were shipped to that country previously in the week.

San Antonio, Tex.—The city council has adopted an ordinance governing electric wiring, a provision of which forbids the use of what is known as "white" or "underwriter's" wire.

Washington, D. C.—The Navy Department is inviting sealed proposals until September 13 for furnishing the Norfolk, Va., Navy Yard with two direct-connected electric generating sets, one switchboard, and thirty lightning arresters. Prospective bidders desiring specifications and blank forms of proposals can obtain same upon application to the Navy Pay Office at Norfolk or to the Bureau of Supplies and Accounts, Navy Department, Washington, D. C.—Consul-General Goodnow sends the following item, relative to the proposed electric street railway of Shanghai, China: The electric overhead trolley system is to be adopted. A concession is to be given for the construction of the line and all accessories to a syndicate or company, to be known as the Shanghai Tramway Company. The concession is to be for thirty, forty or fifty years according to the tender that the ratepayers may decide to accept, and the company is to pay the council a percentage of the total gross receipts for the period of the concession. Notification to tenderers by public advertisement will follow in due course, and the tender finally selected will be submitted to the ratepayers for ratification.

TRANSMISSION PLANTS.

Charleston, W. Va.—The Wilson Aluminum Company, which was chartered some years ago, and which purchased the land on each side of the Kanawha river at Kanawha Falls, is about to begin at that point the construction of a water power plant to generate electricity for the running of all kinds of machinery in the Kanawha Valley, principally mining machinery and electric lights.

Colorado Springs, Col.—The opening of the Colorado Electric Power Company's plant at Canon City is of great importance to the Cripple Creek district. The "Gazette" says: "It is the first attempt in the Rocky Mountain region to use the product of the coal mines near the place of origin for the production of electricity to be used at a distance. In effect it places the cheap coal of the Arkansas Valley at the door of every shaft house in Cripple Creek. It emancipates the miner from the difficulties of obtaining water for the boiler as well as fuel for the furnace, and decreases very materially the amount of heavy machinery which has to be hauled over the steep hills of the district. The successful and profitable operation of the Canon City enterprise will lead to the establishment of similar plants elsewhere, operated either by steam or water power, which will greatly increase the production of established camps and make possible the profitable operation of others which cannot be worked under the present conditions."

Lake City, Col.—The Denver, Col., "Times" says: "Work has commenced on an enormous electric power transmission plant that will utilize water that has gone to waste for centuries. Lake San Cristobal is being dammed up and made to yield force almost beyond calculation, for by a dam fifteen feet high by less than 150 feet long more than 1,675,000,000 cubic feet of water will be stored, and in addition, a ditch five feet deep will render available, according to the calculations of experts who have examined the place, 52,272,000 cubic feet more, and all this may be used at a head of 150 feet although at present much less fall will be utilized. Mines will be lighted and worked by electricity."

Lowville, N. Y.—The Wetmore Electric Company, which has just been incorporated with a capital stock of $40,000, was formed for the purpose of erecting electrical generating works at Belfort on the Beaver river, there being abundance of water power there. The electricity produced will be transmitted to Lowville for lighting and other purposes, the company having obtained a franchise from the trustees. The directors of the Wetmore Electric Company are Oliver P. Hedden and Jacob Strife of Lowville, Supervisor Thomas Glenn of Croghan and George W. Pulver of Syracuse. Mr. Pulver is connected with the Westinghouse Electric & Manufacturing Company.

COMPANY MATTERS.

Sioux City, Ia.—The Electrical Supply Company of Sioux City has doubled its capital. E. C. Spalding has been elected treasurer and purchasing agent, and H. O. Woodruff has taken a position on the road. This company has had a good business and now, with ample capital, it is going to push both jobbing and construction work.

NOTES FROM A CORRESPONDENT.

Albany, N. Y.—The New York Civil Service Commission announces that open competitive examinations will be held in several cities in the State, September 24, for various positions, among others that of assistant electrical engineer.—For the first time on the evening of the 25th inst. the Capitol was fully illuminated in honor of the full completion of the building. It was a brilliant display, as all the electroliers along the front and side of the immense building were fully displayed, as well as those on the massive front staircase, each of which sent forth such a flood of light that a newspaper could be read in any part of the park. The beautiful illumination attracted the attention of crowds of people, all of whom expressed admiration and approval. The electroliers and fixtures were furnished by Mitchell, Vance & Co. of New York City. They are of heavy bronze of most artistic design and finish. The display was magnificent.

Cohoes, N. Y.—The Cohoes Electric Light Company is making arrangements to furnish electric power during the day. Three large new water wheels will be set in position, and several large electric generators will also be put in; power will be supplied throughout the city. It is expected that the plant will be in running order by November 1.

Hudson, N. Y.—The Frisby water power at Stuyvesant Falls has been purchased by the new owners of the Kinderhook & Hudson Railroad. This will be used to run the dynamo which will generate power for the electric cars. The cost of this water power, said to be the best in that portion of the State, was $125,000. The fall from the upper dam is 130 feet, and water will be taken from that point through a steel trunk. The company intends to furnish power for mills and to supply electric light for the neighboring villages.

Schenectady, N. Y.—The employes of the General Electric Company had an excursion to Sacondaga Park August 27. These included the men employed in machine shops 8 and 10 and the experimental department, No. 11, as well as the armature department, No. 15. Fifteen cars were used to convey the excursionists to their destination.

PERSONAL AND MISCELLANEA.

John D. Rively, an inventor of electrical appliances, among them a storage battery for which he made extraordinary claims, died at Pittsburg on the 22d inst.

Walter F. Ford, president of the Winchester Avenue road, New Haven, Conn., died at Pemberton, Mass., on the 17th inst., of apoplexy.

Incandescent electric lights can be inserted in or removed from sockets at considerable height by a new appliance consisting of a long pole to which a metal socket is attached, carrying wires which support a spring clip to encircle the metal base of the globe and hold it while being screwed into position.

A new law regarding transfer tickets on street car lines will go into effect in New York State on the 1st of September. It is applicable to every city in the State in which street cars are run and makes it a misdemeanor for a passenger who has received a transfer to give it away to another person who has not paid his fare, and it will also be a misdemeanor for the latter person to offer it in payment of or in lieu of his fare.

Harvey Hoag, of 514 Massachusetts avenue, Buffalo, N. Y., is the inventor of a contrivance that may have an important effect on the building of trucks for electric cars. He has invented a ball-bearing truck, and the Buffalo "News" says the officials of the Buffalo Railway Company think so well of it that they have allowed him to equip one of their cars with the device. It has been on trial several days and has worked satisfactorily. Mr. Hoag claims his invention will considerably reduce the power necessary to run an electric car.

Nanticoke, Pa., was the scene of a somewhat remarkable series of electrical accidents on the 19th inst., as the following report from the Wilkes-Barre "Record" of the 20th will show: "Harry R. Crowe was instantly killed at his place of business in Nanticoke last night at 10:40 by an electric shock. He was the proprietor of a restaurant on Prospect street and had just finished scrubbing it out when the accident occurred. He reached up to an incandescent light to turn it out and as he did so he touched the exposed wire and fell to the floor dead. No one seems to be able to explain how he received the current unless it was that the light was out of order, or the wire not properly insulated.—Eugene Alexander of Nanticoke also received a severe shock from electricity yesterday. He went into the

cellar and while reaching for a package of goods his hand touched a live wire. He was thrown to the floor by the force of the shock and it was several minutes before he was able to walk. His hand was badly burned.—It was also reported late last night that an unknown man was killed by electricity while standing against an electric light pole in the city park, Nanticoke."

RECENT COMPANY ELECTIONS.

The National Motor Company, St. Louis. Capital stock, $100,000. Incorporators: Herbert H. Hennegin, Peter Hennegin, Oliver D. Harris, Louis A. Allard and William P. Larew, all of St. Louis.

The Clark-McGaillard Engine Company, Camden, N. J.—to construct complete steam and electric plants. Capital stock, $100,000. Incorporators: Chauncey C. Clark, John W. Stoy and Charles P. Watson.

East Washingt n Traction Railway Company (a new organization), Washington, D. C.—Directors: A. M. Bliss, T. J. Brown, Chauncey Marshall, C. A. Barker, David C. Fountain, George Judd, Hora e Crosier, J. A. Mahoney and E. O. Carpenter.

Gloversville Electric Company, Gloversville, N. Y.—President, James Radford; superintendent, John Begley; secr etary, Edgar A. Spencer.

Steelton Light, Heat & Power Company, Steelton, Pa.—President, Samuel Couffer; secretary, E. C. Keller; treasurer, G. E. Coulson; directors: Samuel Couffer, Jerome Hite, John Hess, F. E. Smith, J. J. Barnet, Dr W. H. Seiber, Joseph Fletcher, Michael Harclerode and G. E. Coulson.

COMMERCIAL PARAGRAPHS.

The New York & Ohio Company, manufacturers of the celebrated Packard Transformer, have recently brought out their latest model which is to be known as "Model 98." The results secured on this new model are something considerably ahead of anything that has been secured heretofore in the way of transformer regulation and efficiency. The Electric Appliance Company, Chicago, general Western agents for the Packard Transformer, are distributing special circulars of the same giving tabulated results of a number of tests. The manufacturers of this transformer are prepared to guarantee these results on each and every transformer sold, and a large fall trade is looked for on the "Model 98."

INCORPORATIONS.

The Wetmore Electric Company, New York—to operate in the towns of Lowville, New Bremen and Croghan. Capital stock, $40,000. Incorporators: George W. Pulver, Jacob Strife, Oliver P. Hedden and Thomas Glenn.

The Saginaw & Frankenmuth Railway Company, Saginaw, Mich.—to build an electric railway. Capital stock, $50,000. Incorporators: Henry C. Potter, Jr., James B. Peter, Samuel G. Higgins and William J. Bartow.

The Iola Rapid Transit & Electric Light Company, Iola, Kan.—to build and operate a street railway from Iola to Humboldt and Moren, and to furnish electric lights for those cities. Capital stock, $10,000. Directors: W. S. Hendricks, George A. Berolas, W. S. Evans, J. E. Chastain, L. L. Northrup, Alfred W. Bach and Eugene K. Taylor.

The Dunmore Electric Light Company, Dunmore, Pa. Capital stock, $50,000. Directors: James E. Watkins of Taylor, Anthony J. Irwin of Dunmore, Abraham Dunning, ex-Mayor John H. Fellows and James O. Vaughn of Scranton.

The Hatboro & Horsham Electric Railway Company, Hatboro, Pa.—to build an electric railway one and a half miles long. Capital stock, $75,000. Directors: Magnus Hellstrom, president, Philadelphia; James Crawford, Alfred R. Grandy, Philadelphia; John B. Peddle, Woodbury, N. J.; S. Edward Hagar, Doylestown.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED AUGUST 23, 1898.

[Inventors of electrical apparatus and appliances are apparently taking a rest. The following comprise absolutely all the patents on devices of an electrical nature issued from the United States Patent Office during the week ending August 23. Never before since ELECTRICITY (now in its fifteenth volume) began publication have we seen so meagre a list of electrical patents in the weekly issue of the Official Gazette.]

MISCELLANEOUS.

609,421. Device for Attaching or Detaching Electric Lamp Bulbs. Charles G. Edwards, Albert Lea, Minn. Filed Jan. 24, 1898.

609,639. Electromedical Apparatus. Reinhold H. Wappler, New York City. Filed Nov. 2, 1897.

609,540 Burglar-Alarm. Daniel L. Wartzenluft, Kutztown, Pa. Filed Nov. 16, 1897.

609,745. Diaphragm for Electrolytic Purposes. William G. Luxton, Liverpool, England, assignor to the United Alkali Company, Limited, same place. Filed April 9, 1898.

DESIGN.

29,265. Battery-Plate. Charles T Richmond, Cleveland, O., assignor to the National Carbon Company, same place. Filed July 18, 1898.

TELEPHONE AND TELEGRAPH.

S. M. English, chief electrician of the Postal Telegraph Cable Company at Galveston, Tex., with a body of assistants numbering twenty men, accomplished a splendid piece of work on the afternoon of the 18th inst. Mr. English, as related in the Galveston *News*, had just completed the laying of the large twelve conductor submarine cable through Galveston bay to Bolivar point and was laying back in an easy chair in the Postal's main office when a message was received from General Superintendent Foster that a wire to New Orleans was wanted for immediate use and asked how soon it could be made ready. Mr. English in a nonchalant way replied that nine miles of wire yet remained to be strung before the connection could be made at Bolivar, but he would take a boat to the point and start the work. He reached Bolivar at 1 o'clock and at 1:30 had his gang and hand car ready to begin. The first hour four miles of wire had been strung, the second hour three miles and a half was covered. At 5 the splice was finished at Bolivar, and Galveston began working with New Orleans for the first time through a submarine cable, the building of the nine miles of wire and forming the cable connection having been completed in the remarkably short time of three and one-half hours, said to be the quickest time ever accomplished in telegraph line building.

The Kinloch Telephone Company of St. Louis, which is getting its entire system in trim for the most efficient service possible, is training its "hello" girls in squads of seven. When one squad is sufficiently trained to make rapid switchboard connections, they become instructors to the next squad of seven, and so on. Each day a matron is employed on the top floor of the Century building, where the exchange is located, testing the oral tones of the fair applicants who wish to become telephone girls. Only those possessing well modulated voices are accepted. Then, the applicant must not be short in stature, for she would not be able to reach the telephone keys. In the room where the switchboard proper is located, a testing of the mammoth instrument is in progress. It is what is known as a divided exchange. There are four sections. Three of these have been tested and it will be only a short time until the fourth and last is ready for operation.

At a meeting of the stockholders of the Cumberland Valley Telephone & Telegraph Company held at Chambersburg, Pa., on the 23d inst., the franchise ordinance as passed by the Chambersburg city council was accepted. Work will be commenced at once. In Chambersburg all the wires will be laid underground. The line will be extended to Fulton, Bedford, Huntingdon, Juniata, Perry, Dauphin, Cumberland and Adams counties, Pennsylvania, and Washington and Frederick counties, Maryland.

The main office of the People's Telephone & Telegraph Company, at present at Allentown, Pa., is to be removed in a few days to Columbia, Pa. This company was organized a few years ago and holds a franchise for the construction of a telephone line in Lebanon. The contract for the erection of the new line has been awarded to the Eastern Electrical Construction Company of Philadelphia and work will be started at once. It is the intention of the People's Company to construct a line to Elizabethtown to connect with the line of the Columbia Telephone Company, which will open communication between Columbia and Lebanon at rates much lower than those at present prevailing. The recently elected officers of the People's Telephone & Telegraph Company are: President, H. C. Young, of Columbia; secretary, A. W. Gieskie, of Columbia; treasurer, M. R. Hoffman, of Marietta.

Codes for telegraphic and cabling purposes have always been a necessity for business men, but their great cost has limited their use. The International Cable Directory Company has solved the problem with its Western Union telegraphic code. This work is the most complete public code in the English language. Over a year was spent in the compilation, which contains nearly 150,000 words, making it the largest public code in existence. The directory of the book contains a list of prominent lawyers of New York, Boston, Chicago, Philadelphia, members of the New York Stock and other Exchanges and cable and business addresses of leading merchants, capitalists and manufacturers throughout the United States.

The Union Suburban Telephone & Telegraph Company of Cleveland filed articles of incorporation with the Secretary of State at Columbus, O., on the 23d inst. It is the purpose of the company to construct telegraph and telephone lines from Sandusky to Painesville, with branches in all the counties of the State. The capital stock is $1,000,000, and the incorporators are H. A. Everett, E. W. Moore, James B. Hoge, Charles W. Wason, Frederick Storm, H. W. McGrew and J. B. Hanna, a brother of U. S. Senator Hanna.

The Southwestern Telegraph & Telephone Company opened a long distance telephone office at Palestine, Tex., on the night of the 16th inst. The company gave an entertainment at the Hotel Nolan, at which fully 150 citizens were present. The guests, with long distance receivers at their ears, heard music in Dallas, Sherman, Houston and Galveston, and many conversed easily over the 'phone with persons at points 600 or 700 miles away.

Plucky Telegraphers.

The telegraph service has never been short of heroes. The erroneous statement in a Reuter telegram on the fight at Manila, that during Dewey's bombardment "cable communication was interrupted, the operators at the station, which is in the midst of the forts, having fled to save their lives," has been disproved in a letter from Manila, which puts the telegrapher in an entirely different light. It seems that during the whole of the action of May 1, when Cavite was bombarded by the American squadron, the staff of the cable company, from the superintendent downward, were at their posts, although their office is situated only 200 yards from a Spanish battery, which several times opened on the American ships. Fortunately, however, the latter did not reply. Having completed the destruction of the Spanish fleet and Cavite arsenal, Commodore Dewey lined his ships up in front of Manila, with their guns trained on every shore battery, with the evident intention of commencing a bombardment should a single shot be fired on his squadron from any of the batteries. The operators of the cable company were all this time in their office, transmitting the telegrams which were handed to them, as if nothing unusual was happening. On the evening of May 2 the Hong Kong cable became interrupted. Two of the operators of the company immediately proceeded to the cable house on the beach, which is within a stone's throw of a battery, then threatened by the American guns, and having set up a testing apparatus, found that the cable was broken about ten miles from shore. From that time to the fall of Manila the telegraphers stood by their office day and night, although the building was repeatedly struck and pierced by bullets from the insurgent forces, who maintained a determined attack on the Spanish intrenchments in the neighborhood. Although they were given by the directors permission to retire to a place of safety, they never left their posts.

In Cape Colony, South Africa, the Government controls the colonial telephones. In April, 1898, there were 1,535 instruments in use, and the revenue for 1897 amounted to $66,137.22. There are 869 miles of wire and 780 subscribers. Seven exchanges in the colony work on the single-wire system, but arrangements are now being made to have all lines duplicated, and in future no exchange will be established except on the metallic circuit system. In the course of the next few months the underground cable system in Cape Town will be completed and exchanges established in the suburbs.

The Des Moines, Ia., *Register* of August 20 states that a large party of workmen have been at work several days for the Iowa Telephone Company, placing another circuit between Des Moines and Indianola. The new circuit will complete the metallic circuit between Des Moines and Oskaloosa and the towns in the eastern part of the State, reaching as far as Davenport. The company expects that its service will be greatly improved over the State by the new connection.

A new telephone company is being organized at Amherst, Mass. A sufficient number of subscribers have been obtained for the instruments of the new company to make its success sure.

New Companies Incorporated.

The Newton Telephone Company, Newton, Kan.—to build a long distance telephone line from Newton to Moundridge. Manager, A. R. Champlin.

The Montezuma Telephone Company, Montezuma, Ga.—to construct a telephone exchange. Capital stock, $1,000. Incorporators: Jule Felton and Mrs. C. H. Maxwell.

The Winchester & Lexington Telephone Company, Vine Grove, Ky. Capital stock, $1,560. Incorporators: T. C. Vanmeter, David Prewitt and S. D. Goff.

The Siloam Springs Telephone Company, Siloam Springs, Ill. Capital stock, $1,500, fully paid. Incorporators: G. L. Thompson, John Padgett, John W. Buttz, George Wauer, John B. Wallace, B. A. Curry and W. H. Breckenridge.

The following companies have been incorporated in West Virginia:

New Rochelle Telephone Company, New Rochelle, N.Y. Capital stock authorized, $500,000; subscribed, $100; paid in, $100.

Twelvepole Valley Telephone Company, Wayne, W. Va. Capital stock authorized, $25,000; subscribed, $50; paid in, $50.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

a Leased to Hestonville, Man. & Fairmount Passenger Ry. for 6 % on stock per annum.
b Consolidation of Electric, People's and Philadelphia Traction companies. Fixed charges and all indebtedness of constituent and leased companies assumed by Union Traction Company.
c Practically all shares owned by Union Traction Company.
d Lease to Frankford & Southwark Passenger Ry. assumed by Electric Traction Co.
e Leased to Electric Traction Company.
Controlled by Frankford & Southwark Passenger Railway.
g Leased to People's Passenger Railway at $5 per share.
h Majority of stock owned by People's Traction Company.
i Leased to Union Traction Company.
j Lease transferred to Union Traction Company.
ij Leased to United Traction Co. at a rental of $10,000 per an. in 1866-7-8, $20,000 p. a., in 1899-1900 and $30,000 per annum thereafter, payable semi-annually, rental declared as a dividend semi-annually.
k Dividend of 10 % guaranteed by Reading Traction Company.
l Dividend of 6½ % guaranteed by Reading Traction Company.
m Leased and operated by the Scranton Railway Company, formerly Scranton Trac. Co.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12@12⅛c.; Lake, 12.15@12.25c.; casting, 11⅞@12c.

A meeting of the stockholders of the Bell Telephone Company of Philadelphia will be held on September 20 to vote on increasing the capital stock from $2,000,000 to $4,000,000.

The interest upon the scrip of the Westinghouse Electric & Manufacturing Company to September 1, 1898, will be paid to holders of record of that date. Books closed August 24 and reopen September 2.

The stockholders of the Postal Telegraph Company will hold a special meeting in New York on September 8 to vote upon the proposition to reduce the capital stock of the company from $15,000,000 to $10,000,000.

The Coney Island & Brooklyn Railroad Company reports for the quarter ended June 30: Gross earnings, $274,753; net earnings, $145,969; other income, $29,142; charges, $156,261; surplus, $18,850, against $17,207 in 1897.

The Bloomington & Normal Street Railway, as successor to the Bloomington City Railway, has made a mortgage to the Illinois Trust & Savings Bank of Chicago, as trustee, to secure an issue of $250,000 first mortgage 5 per cent. bonds.

The stockholders of the American Telephone & Telegraph Company, the company controlled by the American Bell Telephone Company and owning that company's long-distance telephone system, will vote September 8 upon a proposition to increase the capital stock from $20,000,000 to $25,000,000.

The first mortgage bondholders' committee of the Terre Haute (Ind.) Street Railway Company has prepared a bondholders' agreement and has secured the deposit of more than a majority of the bonds thereunder. The limit of time for receiving deposits at the Illinois Trust & Savings Bank, Chicago, has been fixed at September 15.

The sale of the Suburban Traction Company of Orange, N. J., was completed on the 24th inst., on which day the purchasers of the road completed the payments, fulfilled all the conditions of the sale and were given full possession. Receiver Whittlesey represented the Suburban Company and Charles A. Sterling, Bernard M. Shanley and John Ely the purchasing company.

The Chicago "Dispatch" says that "of the $2,000,000 of Commonwealth Electric Company bonds recently issued it is announced that $500,000 have been placed in London with the London-Scottish American Trust through Aldis, Northcote & Wilson. In addition $1,000,000 have been placed in Chicago. N. W. Harris & Co. are offering the remaining $500,000 of the bonds to the public."

A notice calling in its issue of 5 per cent. bonds has been sent out by the Newark (N. J.) & South Orange Railway Company. The issue aggregates the sum of $500,000, and the call is the result of an arrangement with the North Jersey Street Railway Company, whereby the latter absorbed the Newark & South Orange Company. Now 4 per cent. bonds will soon be floated by the company, it is said.

The New York State Railroad Commission has authorized an increase of the capital stock of the Catskill Electric Railroad Company from $30,000 to $400,000. The road was originally built to be operated for a distance of only about two miles from Catskill village, but it now plans to extend its scope by running out to Windham and Cairo and other villages in Greene and adjoining counties, making a line 16 miles in length.

The General Electric Company of Schenectady has filed with the Secretary of State at Albany a certificate of reduction of capital stock as follows: Common stock, from $30,460,000 to $18,276,000, and preferred from $4,252,000 to $2,551,200, making the total capitalization of the company $20,827,200, or a reduction of $13,884,800. The amount of capital actually paid in to the corporation was $34,712,000, and the amount of debts and liabilities is estimated at $6,269,800.

The United Electric Securities Company, Boston, invites proposals for sale to it of so many of its collateral trust 5s, bonds of the fifth, seventh, ninth and tenth series, as can be purchased with the following amounts of cash: Fifth series, $9,778.91; seventh series, $3,893.75; ninth series, $47,553.75; tenth, $12,800; total, $74,026.41. Sealed proposals will be received at the office of the company in Boston until 12 o'clock M. August 31. All bonds accepted will be paid for September 2 on delivery, together with accrued interest to that date.

The St. Louis "Republic" states that St. Louis capitalists are at work on a scheme, which if successful will place them in possession of the rights and franchises to operate all the street railroads in Havana as soon as the terms of peace are sufficiently defined to enable them to proceed. It is the intention to put in a system of trolley roads in Havana that will completely cover the city. Not only is it the intention of these parties to operate a complete railroad system in the city of Havana, but also to extend lines out into the surrounding country, one in particular being projected to a fine bathing beach about 12 miles beyond the city limits.

Orders have been entered in the United States Court at Detroit for the sale of the Consolidated Street Railway Company of Saginaw to satisfy a claim of the Boston Safe Deposit & Trust Company, in trust, for $253,719, subject to receivers' certificates of $30,000. Also for the sale of the Union Street Railway Company of Saginaw to satisfy the claim of the Boston Safe Deposit & Trust Company for $361,149.75, subject to receivers' certificates of $59,000. The sale of the Consolidated Company may be made any time after August 16 and of the Union Company after November 26, and in both cases the bondholders or any party or parties at interest may be the purchaser. The court has dissolved the injunction issued at the instance of the city authorities April 20, 1897, for the forfeiture of the charter, holding that the charter had not been forfeited as against the bondholders.

The Chicago "Inter-Ocean" says: "By far the most novel use to which street cars in Chicago have yet been put is now being arranged by the Chicago General Railway Company on the Southwest Side. This road, famous for its ideas and its enterprising schemes, is planning to go into the draying and freight transferring business by trolley. If everything works as anticipated a few months from now will see curious flat-topped cars loaded with merchandise scurrying about on the Twenty-second street tracks. The idea was first suggested by the great number of steam railroads which the Chicago General Railway's tracks cross. In the thirty odd miles of line operated by the company no less than seventeen steam roads are intersected, and all in a factory and manufacturing neighborhood. The great amount of freight being hauled, transferred and shipped throughout the locality immediately showed the peculiar advantage which some means of cartage by electricity would possess over the present methods."

The stock of the Big Consolidated Railway, Cleveland, O., was raised several points last week through the efforts of the Andrews-Stanley and Everett-Moore factions to get possession of enough shares to control the election for directors in January next. The price of the stock at the beginning of the struggle was 60 and it reached 76¼ before the reaction came. The Cleveland "World" of the 25th says that interest in the contest had at that date died out completely and the market for the shares was as dull as it well could be. "There is reason to think," says the "World," "that one or the other of the warring groups of millionaires involved has secured the shares necessary to control, and that efforts will be made from time to time to unload shares on the excitable speculative public by the defeated faction, as long as the war scare can be worked." During the fight for control, according to the paper quoted, W. P. Todd of Chicago, formerly of Cleveland, asserts that he realized the handsome profit of $47,500 out of the sale of the stock.

ELECTRICITY.

Vol. XV. NEW YORK, SEPTEMBER 7, 1898. No. 9.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4081 Cortlandt.

SUBSCRIPTION RATES:

United States,	$2.50
In Clubs of Five or More,	2.00
Foreign Countries,	4.50
Single Copies,	10 cents

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

The Outlook in the Electrical Industry.

Now that peace between this country and Spain is practically assured, it might be in place to consider what effect the changed conditions will have upon the electrical industry. During the past few months we have acquired either by conquest or annexation extensive territorial rights in various parts of the globe, which, judging from their present state of civilization, should shortly afford excellent opportunities to the enterprising electrical engineer and manufacturer. The islands which have come under the control of the United States as a result of the war are without exception lacking in up-to-date methods of manufacture and sorely in need of transportation facilities, as might readily be expected of former colonial possessions of such a conservative and hide-bound country as Spain. Cuba, the largest and most important of the islands, boasts of a few electric lights in its principal city which from all accounts are in need of modern apparatus to make them satisfactory. There are telegraph lines it is true, but no organized telephone system, and electrically propelled street cars are conspicuous by their absence. For an island with an area of 41,655 square miles, or in other words, about the size of the State of Pennsylvania, and with a population of almost two millions of people, this is certainly not a very excellent showing. The amount of electrical apparatus which this country exported to Cuba during the fiscal year which ended just previous to the opening of the war amounted to but $30,375, which, although considerably more than was sent by this country to any of the other islands now under our control, is an insignificant amount as compared to similar exports even to such remote South American countries as Argentina, Brazil or Colombia.

Porto Rico, which has a population of over 800,000 and an area of 3,550 square miles, is fairly well off as far as telegraphic facilities are concerned, and is provided in certain localities with telephone systems and electric lights. Our exports of electrical machinery to this island for the fiscal year just previous to the war amounted to but $22,801, which, taking into account the difference in area and population, would seem to be a better showing than in the case of Cuba.

The Philippine Islands however, owing probably to their great distance, make the poorest showing of all, there having been but $3,054 worth of electrical apparatus sent there from this country during this same fiscal year. Now that a stable government is assured for all these islands, and with their undeveloped resources, there should be a wide field for electrical enterprise, not only in the telephone and street railway lines, but in various industrial and manufacturing lines as well. That new markets for electrical apparatus of American manufacture will be created cannot be doubted, as already several companies have been organized to build and operate street railways and lighting plants in both Cuba and Porto Rico as soon as their new governments are established.

This opening up of Cuba, Porto Rico, the Philippines and Hawaiian Islands to American enterprise should do much toward reviving the electrical industry in this country and lifting prices to a safe and remunerative point, which cannot be said to have prevailed of late. Likewise the restoration of peace should be the signal for the starting up of various enterprises in street railway and lighting lines which were held back awaiting a better money market and the termination of the war.

* * *

Electricity as a Dissipator of Fog.

The recent accident to La Bourgogne, principally due to fog, has brought out various suggestions from more or less eminent men as to a means of warning vessels when in close proximity to one another, or of some method other than the auricular signals now in vogue. Probably the most original suggestion that has yet been advanced is that of dispelling a fog by means of electrical discharges. Mr. Alexander McAdie in a recent contribution to the *North American Review* advocates some such method, and gives his reasons for so doing. At the outset he states that air at sea level at a temperature of 80 degrees Fahrenheit, half filled with moisture, has eleven grams of water vapor to each kilogram of air. If the temperature is lowered, say 15 degrees, through a change in the pressure, the air will become saturated with water vapor, or in other words, will have all it can hold. Mr. McAdie then goes on to say: "If the mixed air and vapor can be lifted about 4,000 feet, the rain engineer can ordinarily form a cloud or fog. Conversely, if he can increase the pressure and supply the requisite amount of heat, he can alter conditions so that no fog forms, or, if it has formed, cause it to disappear. Provided we can control the thermo-dynamic conditions, we can condense the invisible vapor of the air into visible cloud, and, on the other hand, change the visible fog into invisible vapor."

In Mr. McAdie's opinion this desired result might be accomplished by a method suggested by Prof. Oliver Lodge, the well-known English savant, some time ago in a lecture before the British Association at Montreal. At that meeting Prof. Lodge related some experiments which he had carried on with a view to discovering a method of dissipating dust fog, which frequently gathers in towns and cities. He stated that

he had found that a bell jar filled with magnesium smoke or with steam could readily be cleared by an electrical discharge. Experiments were also carried on in a room filled with thick turpentine smoke, it being definitely shown that the air could be speedily cleansed of its solid particles by discharges of electricity at a high potential. In 1887 Prof. Lodge, while en route to this country, was detained for several hours by a very thick fog, regarding which he subsequently wrote as follows:

"Fog is an unmitigated nuisance. Electric light is powerless to penetrate it, and as we lay there idle it was impossible not to be struck with the advisability of dissipating it. It is rash to predict what can be done. It is still rasher to predict what cannot be done. I would merely point out that on board a steamer are donkey engines and that these can drive a very powerful Holtz or Wimshurst machine, one pole of which may be led to points on the masts. When electricity is discharged into fog on a small scale the fog coagulates into globules and falls as rain. Perhaps it will on a large scale, too."

Mr. McAdie thinks that the time has now come to try Prof. Lodge's suggestion, made over ten years ago, and points out as one of his reasons that all steamships and even ferry boats of any size are now equipped with dynamos which could readily be made to generate economically high potential currents of from forty to fifty thousand volts by the use of suitable transformers in series. He is of the opinion that "within a reasonable distance such discharges would certainly dissipate the fog and clarify the air." On the other hand, he admits that fog might be so dense as not to be affected by such electrical discharges, but thinks such cases would be exceptional. There would seem, in our opinion, no reason why such an experiment on a large scale should not be tried, as it could be done at comparatively little expense; whether it would prove successful, however, is debatable. That a discharge of high potential electric currents from a ship will dissipate a heavy fog at any considerable distance from the vessel is scarcely to be expected, and unless the area cleared were of at least moderate size, thus allowing the lookout to see a considerable distance ahead and on either side, it would not render ocean travel materially safer than it is at present.

* * *

The Use of Roentgen Rays in Cuba.

In an editorial which appeared in our issue of July 6 we described at some length the excellent results obtained by means of the Roentgen ray in an Indian campaign as described by Surgeon-Major Beever of the English army in a lecture before the Royal United Service Institution. At that time the Roentgen ray apparatus had not been given a fair trial in Cuba in locating bullet wounds, and there were many who still advocated the use of the probe, looking upon the X-ray apparatus as altogether too complicated for practical use in field hospitals. That the Roentgen ray apparatus may be used speedily and effectively is now clearly proven by Dr. William M. Gray, the microscopist of the Medical Museum in Washington, who was detailed to the hospital ship Relief by that institution for surgical work, with special reference to the diagnoses of gunshot wounds by the Roentgen rays. In an interview with Dr. Gray, which was reported in a recent issue of the New York *Sun*, he is credited with the following statement: "One thing this war has taught is that the probe in all its forms has gone out of use. No more searching blindly in a man's body for the bullet; no more danger of blood poisoning from the introduction into the wound of instruments of search. The fluoroscope tells us instantly where the projectile has imbedded itself, and we have only to cut it out as if it were there before our eyes. The ingenious electric probe and all similar devices have seen their day. In all future battles experts in skiagraphy will be attached of necessity to the medical corps, and the work of the surgeons will be materially assisted by their precise indications. We took out bullets by the pint on board the Relief, and almost without exception they were located by the X-rays."

As to the time consumed in photographing the patients and in developing the X-ray plates, Dr. Gray stated that the whole operation consumed but a few minutes. It took ordinarily not over five seconds for a wound in the hand, thirty seconds for one in the foot. He further mentioned a case where a man was wounded in the right shoulder by a Mauser bullet which plowed its way on around the chest walls under the deep muscles and finally lodged in the arm, shattering the humerus. He said: "Here was an odd condition, a wound in the right shoulder but no bullet; the bone of the left arm broken but no wound. How long do you suppose it would have taken to find that bullet by probing? It did not take us one minute to find it with the X-rays."

That the Roentgen ray apparatus can be advantageously made use of to alleviate suffering during a campaign is not to be doubted notwithstanding arguments to the contrary. This fact would seem to be clearly proven by the statement of Surgeon-Major Beever of the English army regarding the use of the X-ray in India and by Dr. Gray's experience in Cuba, who says: "In many cases we save hours of vain searching, and not infrequently we save the soldier's life."

Under the Searchlight.

Notes and Comments on Various Topics

ACCORDING to a statement in the N. Y. *Commercial*, credited to "a member of one of the large electrical organizations," "Eugene Griffin, vice-president of the General Electric Company, is at present in Porto Rico with the First Regiment of Engineers, of which he is colonel, and it is understood that he will study the country thoroughly in the interest of the company of which he is an officer. Upon his report will depend to a great extent the plans of the General Electric Company regarding the invasion of Cuba by their agents." This is placing Col. Griffin in a rather unpleasant light, and probably a false one, but if it is true and he carries a copy of the Bible with him, he would be doing his conscience a favor by reading a passage in the 6th chapter of Matthew, 24th verse.

* * *

PRESIDENT M. K. BOWEN of the Chicago City Railway Company discovered that the fender ordinance introduced in the city council provided that every car operated by a street railway company must have a fender, and being in a jocular mood he at once wrote a letter to Mayor Harrison in which he said that "the company which he represents does not want to do anything illegal, but its officials do not see how they can put fenders either on trailers or horse cars." A copy of the letter was sent to Acting Mayor McGann, who took every word seriously, and said the council would be asked to amend the ordinance at its next meeting.

THE following appeared in *Pearson's Weekly*:

Wild Man of Borneo—"I tell you the manager of this show is a smart chap."

Bearded Lady—"In what way?"

Wild Man—"For cases of emergency. While you were out this afternoon, the current from the Electric Girl struck the Man with the Iron Jaw, who was seated next to her, and nearly set the platform on fire, but the manager saved the show."

Bearded Lady—"What did he do?"

Wild Man—"He seized the India Rubber Man, shoved him in between the couple, and insulated the Iron Jaw Man."

THE Dustless Roadbed Company is the name of a Philadelphia concern which has been organized on a plan very different from that of the numerous incorporations that are springing into existence without any visible means of support. Its motto is "down with the dust." This unique concern, as we learn from the Philadelphia *Stockholder*, has just completed "oiling" eleven miles of the New York, Philadelphia & Norfolk Railroad at an expense of $75 a mile. One oiling is said to be sufficient to keep down the dust on a road for three years.

* * *

OTIS, ME., is said to have recently experienced the severest thunderstorm in its history. Some of the freaks of the lightning were remarkable. At the place of a man named Hanscom, two families occupied the house. In the front part an old man was seated in an armchair reading the Bible. A ball of fire rolled lazily in at the window, danced along the window ledge a second or two, and then rolled into the old man's lap and across the open Bible. He experienced no shock whatever, except a blinding sensation, but the metal clasps of the book were melted and ran to the floor, while across the pages of the book was stamped a miniature photograph of a large apple tree in the dooryard, near the window. Some minutes after the ball had passed the old man tried to rise, but was firmly held to his chair by some mysterious force. After an hour or more of effort by members of the household, a liberal bathing of vinegar and other remedies, the chair finally loosed its hold and he was able to rise. He felt no ill effects from his experience. The ball of fire, after dropping from the book, had struck the floor and bounded to the ceiling, passing out through the cracks in the top of the partition into the sleeping apartments of the Hanscoms, where young Mrs. Hanscom was seated with her baby in her arms. It came toward her a swaying ball, moving back and forth until it struck her full in the face and disappeared. Eight of Mrs. Hanscom's front teeth disappeared with it, and were never found. Her chair was tipped forward, and she was found unconscious, her head and feet resting on the floor, still retaining her position in the chair as if it were upright instead of resting upon her. It was some time before she could be revived. Strange to say, the baby was unharmed.

THERE are several styles of criticism or fault-finding to be met with in the columns of the modern newspaper. Some of them are spiteful, some peevish, some cynical, some impertinent, some that mash like a club, some that raise welts like a whiplash, and some that are as undefinable as the hues of a chameleon, among which may be classed the following, which we find in the Riverside (Cal.) *Enterprise*, under the heading "Our Electric Service":

A Washington official of wide experience recently said the heads of departments had just two kinds of men to deal with—men who went ahead and did the things they were expected to do, and men who always had the best of excuses for their continued failures. The fellows

who are running the electric power plant over at Redlands seem to belong in this latter category.

We think more and more of the electric light and the power that runs the rattling Mergenthaler and the big press every day. We have learned what an uncertain thing it is, and how dark the world seems when the deft and dainty-fingered monkey wrench manipulator over toward Smiley Heights opens the sea valves and allows the juice to escape in the direction of the Mojave desert.

As an electrician, we would probably be quoted below par. We don't know the difference between an armature and a ligature, and it is our impression that the volt was discovered by Voltaire, but we have a diseased imagination and a reputation for mendacity that entitles us, we believe, to consideration as an applicant for the place now occupied by the apologist-in-chief of the Redlands plant.

Light is a beautiful and holy thing, but it is becoming so scarce over in this neck of the woods that our contemporary, the *Press*, is thinking of adopting raised letters to enable its readers to absorb the contents after dark. Moreover, the sense of touch is being dangerously developed in our midst, several citizens having been touched within a week.

We trust that there will be an improvement soon in the service—not that we care to see any one killed, but it might be done without notifying us of the festival in advance.

Eugene F. Phillips' Clam Dinner.

This popular annual event, which is looked forward to by the electrical fraternity with as much delight as the coming of a circus affords to a village urchin, is announced to occur at the usual place, Pomham Club, Providence, R. I., on Saturday next, the 10th inst. The invitation cards are out. A right royal Rhode Island clambake is the leading gastronomic feature of these dinners, and adds unction to the speeches and other doings which combine to make the occasion so pleasant that every participant talks of it for weeks and then stores it away in his memory as a cherished experience. This being the twentieth annual recurrence of the festival, a company more numerous than usual may be expected, and consequently enhanced enjoyment; even the bivalves themselves, in view of its being the twentieth anniversary of their employment by the veteran manager of the American Electrical Works in contributing to the happiness of his trade friends, are likely to present themselves in their best form and condition. Lunch at 11:30; bake opens at 2.

Meeting of the American Street Railway Association.

As we go to press we are informed that the members of the American Street Railway Association have just convened in Boston. That the work of this Convention will be of the high order of that of other similar gatherings cannot be doubted. The proceedings of this their Seventeenth Annual Convention, and a full account of the excellent work that this able body of men is expected to accomplish, will be given in our next issue. The full programme of the meeting was given in last week's ELECTRICITY.

BOILER FEEDING BY INJECTORS.*

BY JAMES WHITCHER.

If with thoroughly open and impartial minds we start to argue out the problem of boiler feeding, we find ourselves led almost irresistibly to the conclusion that injectors should afford absolutely the best and most economical of the several methods available, so much so, that we begin to wonder why it is not the universal method, for its use entails no waste of heat, and its mechanism is of the simplest possible character, and of cheap, compact and durable construction.

Yet, in practical circles, we find that, apart from the strikingly unanimous confidence that is reposed in it for locomotive purposes, the method is viewed with deepest and general mistrust. One scarcely ever hears a good word for injectors applied to stationary boilers. Engine drivers and stokers as a class would have none of them if they could help it and where a pump and injector are fixed together to share the work the pump will be used, though in the last stage of ruin, while the injector is left to rust in idleness. When a reason is sought for this strong prejudice the answer is, that injectors cannot be relied upon, and that they use too much steam.

Now, it is evident at once that the former charge is an unjust one; for if injectors are not to be depended upon for general purposes, they would be equally unreliable for locomotives, and that is contrary to experience. Besides, plenty of instances can be adduced, particularly relating to low pressure boilers, where, in spite of the prejudice of attendants, single injectors (without a stand-by) have performed their duty in a thoroughly satisfactory manner for long periods, and required scarcely any attention or overhauling. It is, in fact, often the valves that give the greater part of the trouble that there is.

The second charge is of more importance, and it has undoubtedly a real foundation in fact, although the why and wherefore of it is a veritable puzzle, in view of the absolute absence of any avenue of escape for the energy that is apparently wasted in very liberal measure. Usually on the starting of an injector, the boiler pressure begins falling in a rapid, decisive manner, that means some anxious moments to the stoker, especially if he has the misfortune to be located in a district where smoke is under a strict taboo, and he has to be particularly canny with his dampers. The recovery is comparatively quick, but in the stoker's mind this does not go down to the credit of the injector. He ascribes it rather to the cessation of its baneful influence; and even when he does realize that this recovery is quicker than it would have been if the water had been pumped, there is not much comfort for him, for it is the fluctuation of pressure that concerns him most; and his grievance is that he cannot avoid it except by the short and frequent system of dosing his boiler, which he naturally abhors.

Probably the objectionable characteristic in the working of injectors is largely due to the use of a size too large for its average duty. The feed water is supplied at too rapid a rate for the furnaces, and this rate of influx is not visible as it is in the case of pumping and is not so easily regulated. The intangible mode of operation of injectors is necessarily a considerable obstacle in the way of confidence in their use, and a simple and effective indicator fitted to them, showing the rate of flow into the boiler, would be of much service. An injector so fitted, and constructed so that the rate of feed could be regulated over a long range, would be the equal of a pump in convenience of working. But for lack of these features the stoker has certainly a true bill against the injector, and good reason for his preference for a pump. The latter gives him a sensitive means of controlling the pressure, additional to mere manipulation of the furnace, whereas the injector practically deprives him of it—not, of course, that it is impossible to regulate the feed with some forms of injectors, but the requisite judgment and familiarity in using the apparatus is not so easily acquired.

There is good reason for the belief that injectors are big steam eaters, for under many conditions they must be delivering the feed nearly at boiling temperature and sufficient steam is consumed to effect this. Thus supposing a supply of feed water for half an hour's consumption is put into the boiler in the first five minutes. If pumped, the cool water lies low in the water space, and takes heat, mostly from the furnaces, and at a fairly constant rate throughout the whole period of 30 minutes. But if injected, the feed is not only delivered, but also heated nearly to steaming point, within the short period, and the extra duty is done, not direct by the furnace, but by the store of steam. Steam is made quicker during the subsequent 25 minutes, but the effect is a pronounced fluctuation of pressure, being a rapid fall followed by a slower rise; and the variations are too sharp to be modified easily by the mode of firing. The excessive draught on the store of steam produces almost as serious a fall of pressure as would result if the cool water from the pumps were to be sprayed into the steam space instead of delivered in a sluggish stream below the water level.

These fluctuations are not actually so very serious an objection to the injector, and they would be less significant if stokers would only educate themselves up to an intelligent use of the appliance. The chief trouble is that it forms so ready a handle for aspersions on the economy of injectors. Immature reasoning faculties find in the traveling back of the steam gauge, when the injector is turned on, triumphant proof of its wastefulness too conclusive to be confuted by any argument to the contrary; and it is useless generally, in the face of this conviction, to argue the impossibility of there being any real waste.

However, there are two counts on which indictments may be urged against injectors with a greater show of reason. These are that their use depreciates the efficiency and working capacity of the boiler, and the efficiency and capacity of the feed heating devices, if any. Now, as to the first, we have it on good authority that live steam feed heaters, far from diminishing the efficiency and capacity of boilers, increase them by upwards of 10 per cent. This surprising fact was indubitably established some time ago by the experiments of Kirkaldy and others; but it is not at all clear yet whether it applies equally to all kinds of boilers and to all conditions of working. If it does, it is no more possible to maintain that injectors, any more than feed heating devices of any kind, have a deleterious effect on the working activity of the boiler. Their influence, instead, should be quite the other way.

Were it not for the startling result of the above-mentioned investigations we should not have much hesitation in assuming that a cold feed would induce a more rapid transmission of heat than a hot feed, and therefore that the work proper obtained from the boiler is greater in the former case than in the latter. It tells us, however, that the reverse is the case; and the reason why is very obscure, no satisfactory explanation being possible with our present knowledge of the operation of heat transmission in a boiler. But the practical meaning of it all is that feed heating makes for economy, not only because of the net amount of heat added, but also because of the mere fact of its elevating the mean temperature of the boiler contents.

As to the second count we are on surer ground. For instance, it would certainly be a mistake to pass the feed water from an injector indiscriminately through an exhaust feed heater, for little heat could be gained, and some might be lost. As most injectors are unreliable if supplied with water at a greater temperature than 100° F., we cannot gain much by drawing the supply through such a heater beforehand, and there is always the risk and inconvenience of its becoming overheated. Likewise with economizers; unless there is a substantial difference between the temperature of the feed delivered from the injector and the economizer temperature the feed-heating device becomes of negative value.

We can now perceive that in this bye-path lurks the one real and economical objection against the injector, for evidently the price of its use may be the sacrifice of feed heating by the waste heat, and it is of serious magnitude. Suppose, for instance, that the working pressure is 140 lbs., that we feed the boiler by a pump of 50 per cent. efficiency through an exhaust heater, raising the temperature of the feed from 100° F. to 200° F. One pound of steam will pump 100 lbs. of water, and the heat thrown away in the pump exhaust is 1,120 British thermal units, whereas the heat abstracted from the heater is 10,000 units. An injector would save the former quantity and reject the latter, which indicates a very

* From the *Electrical Review*, London.

large balance in favor of the combined pump and heater.

From the practical point of view, therefore, we see that it is bad policy to use an injector where feed heating is possible, and that it is also bad policy to use a pump, unless in conjunction with a feed heater. Thus there is a very clearly defined line of demarcation between their two respective "spheres of influence" and utility.

At first sight it does not appear as though the mere question of mechanical efficiency could have any decisive influence on the application of injectors to boiler feeding. It seems quite beside the point, seeing that thermal efficiency is the real desideratum, the which, in this case, is unity. Theoretically, boiler feeding does not imply any expenditure of work; it is simply the exchange of a volume of steam for an equal volume of water; and, since with suitable temperature conditions the steam may be condensed by and form part of the volume of water, there need be no loss of heat in the exchange. We assume, of course, that the levels of water in the boiler and feed tank are the same. There is no work lost, except in the friction of motion; and this appears again as utilizable heat; hence no heat disappears on conversion into work.

Where the mechanical efficiency of the injector becomes a significant factor is, that it may be so bad that there is necessarily a large difference between the feed water as supplied to it and as delivered from it. This temperature difference constitutes a very accurate and, indeed, absolute measure of the injector efficiency. It shows definitely how many unit volumes of steam have been absorbed to deliver each unit volume of water. If the difference is large, the function of feed heaters is, as we have seen, very seriously interfered with, and so a very momentous, though indirect, disadvantage is introduced.

An injector which could take water at, say 60° F., and deliver at 80°F., through a heater in the boiler, or take water from the heater at, say 200° F., and deliver direct to boiler, and do so over a full range of varying loads, could encroach very successfully on the province of the pump. The second condition is apparently impossible unless the water supply is under pressure and the former is probably impracticable over a range of loads, and anything in excess of this would, under average conditions, make the combined efficiency of injector and heater decidedly less than the combined efficiency of pump and heater.

Hutton, in his valuable treatise on "Steam Boilers," states that the average performance of injectors is to deliver from 10 lbs. to 18 lbs. water per pound of steam. Now, at 140 lbs. working pressure, about 200 lbs. water should, in theory, be exchanged for 1 lb. of steam. Hence the mechanical efficiency of injectors ranges below 10 per cent. With the highest theoretical efficiency of exchange, i. e., 100 per cent., the temperature rise of the water injected would be somewhere about 5° F. But Hutton gives a table for the average rise of temperature in practice, which states that with a working pressure of 40 lbs. per square inch, the rise is from 100° F. to 145° F.; at a pressure of 100 lbs. it is from 120°F. to 175° F.; and at 200 lbs. pressure it is from 145° F. to 255° F. It may be possible to obtain better performances than these; but as they stand it is evident that exhaust feed heating in conjunction with such injectors would be scarcely wise.

Apart from the question of feed heating, the injector merits preference above all other appliances for boiler feeding. It is so neat, compact and easily applied, and, at the same time, cheap and effective, that it ought to be in better and more general favor than it is. It would reap better opinions if attention were given to the following points in installing it: Firstly, as a precautionary measure, two injectors of equal size should be used in each instance, and their combined capacity should be about equal to the maximum rate of feed required and ought not to greatly exceed same. Secondly, the two injectors should be mounted quite independently of each other, and so that either can be easily dismantled and overhauled during working hours.

Indeed, these are advisable modes of procedure in the case of any boiler feeding or like appliances. Apparatus that can only be overhauled after hours is bound to receive the scantiest possible attention, and of a sort that is too hurried to be intelligent. Thorough duplication, if not carried to excess, is the truest economy in the long run, saving much in the way of emergency repairs and renewals and securing the best working conditions, and where feasible, it is only just to the attendants to provide it. For steam raising plant is especially exacting in the overtime duty it demands of them, and some thought ought to be given to the lightening of those duties in designing of same.

POWER TRANSMISSION BY BELTS AND PULLEYS.

Such enormous amounts of power have been wasted in the past by belts and shafts and gearing generally, says the *Electrical Review*, London, that the question of a little more or less has not attracted the attention it should have done. Probably, in the future when electrical driving becomes more common and the power to drive a machine can be so easily found, it will become apparent that the direct driven machines use so much less power than belt driven machines that attention is likely to be directed to belts with a view to reducing their frictions and other wastes. Mr. C. L. Redfield some time ago drew attention to the subject in the *Engineering Magazine*. He is of opinion that belts have been neglected in the rush after electrical transmission, this neglect of old methods being a usual custom, and often leading to undue condemnation. In designing a belt system there are many items to consider in arriving at a suitable compromise. There is the shaft diameter and speed, the diameter and face of the pulleys and the belt size, and these are capable of a large number of combinations.

The first loss in a belt is that due to bending it round the pulleys and unbending the same. Though small the loss occurs at four points in each belt. To transmit a given power there must be so many cubic inches of belt pass any given point in a given time. To do this we may either run a large belt slowly or a small belt quickly. The product of area and velocity must be constant.

As the bending force varies as the breadth and as the square of the thickness and as the amount of bend, a 2-inch belt offers simply twice the resistance of a 1-inch belt; a belt ¼-inch thick offers four times the resistance of one only an eighth thick. Hence a 1-inch belt of a quarter thickness has double the resistance of a belt 2 inches by one-eighth. Yet they are equal in area. In respect of shafts their resistance varies as their speed and diameter, and their power varies as their speed and as the cube of their diameters. Thus a 2-inch shaft is eight times as powerful as a 1-inch shaft, and a shaft at 200 revolutions transmits double the power of a shaft at 100 revolutions. Now loss by friction varies as the load or journal pressure multiplied by the speed.

Considered alone the friction speed is a direct function of the diameter: the weight varies as the square of the diameter so that the friction loss varies as the cube of the diameter. A shaft alone, therefore, has an equal frictional loss whatever its diameter. If a shaft carries other load than itself, every reduction of diameter with consequent increase of speed increases the friction. Larger and slower shafting is thus economical when a shaft has extraneous loading. But with high speed of belts the pull of a belt diminishes, and so far a high speed shaft will have a less load on it than if it ran more slowly. This points to economy with small high speed shafts. But the gain becomes small as speeds become high especially, because the friction surface moves a greater distance under the load. Moreover, larger narrow pulleys are heavier than smaller wider ones and add to the load. Centrifugal tension demands greater tightness and the maximum velocity is limited to somewhere from 4,000 to 7,000 feet per minute. The lower limit, we think, is more likely to be the more economical.

A system of shafting is assumed for illustration, driving four machines by countershafts placed two on opposite sides of the main shaft. The calculations are made on the basis of journal friction alone, though some of the changes made from the original plan, as the use of larger pulleys, bring in other economics. The example shown is quite an ordinary arrangement. Calling the coefficient of friction $= k = .075$ and taking out all the pulls and loads, he finds the friction of a 20 horse-power transmission to be 3.602 horse-power. Inspecting the diagram shows that the pulleys driving the countershafts are not close together. By reversing each opposite pair of countershafts, end for end, their driving pulleys come close together, and their belt pulls on the main shaft now partly balance one another.

Again by doubling the speed of the main shaft and halving the pulley diameter the load on the main bearings is reduced, at the expense, however, of the friction velocity, and the result is a loss. Such a change is unprofitable. It does not pay to reduce the 3¼-inch shaft to 2½-inch with reduced belt pulleys. Speed the shaft up and keep the same pulleys and they can be made narrower, and smaller belts may be used having only one-half the pull. This reduces the load on all the shafts and only increases the friction on the main shaft. Starting with an original resistance of 1,584,615, the reversal of the countershafts reduced this to 1,191,575. The next change reduced it to 819,354. If, however, the main shaft had been kept down to 100, and the belt speed had been got up by enlarged pulleys, the countershaft losses would remain as in the last case, but the main line friction speed would be reduced by more than the load would be increased and the total resistance becomes now 720,543.

The next trial is to increase the pulley diameters again all round and put the main shaft again up to 200 revolutions. The result all round is a saving and the total resistance becomes 558,162. But he now observes that the pull of opposite countershafts is uneven upon the main shaft, and he reduces the pulleys on one of them so as to get a balance. This reduces load and friction, for it transfers pull from a large to a small bearing at a lower speed. Having obtained the balance on the main shaft, he then again increases pulley diameters in proportion, and gets up the belt speeds again, and obtains a final resistance of only 463,120, or less than a third of what he began with. The general deduction seems to be to balance pulls on a main shaft driving to two sides. To keep such opposite pulls upon closely contiguous pulleys. To keep shaft speeds low and pulley diameter high. It is, of course, the difficulty in practice to get pulleys as large as one would like. There is not room for them. Designers also look to first cost of pulleys and are exceedingly apt to forget belts, yet where belts are long and good their cost may go a long way towards increased pulley cost. Belts can be narrowed as much as pulley diameters are increased, while the pulleys themselves may be narrower, and they will be easier for the belts and have better grip.

The General Electric Company owed on July 1, 1898, $1,488,200 accumulated dividends on its preferred stock. These dividends have not been paid since July, 1893. The rate of interest is 7 per cent. per annum. Neither have any dividends been paid on its common stock since August, 1893.

LODGE'S SYSTEM OF SYNTONIZED WIRELESS TELEGRAPHY.*

That the Marconi system of wireless telegraphy has achieved considerable practical success is well known. Messages have been sent over a distance of 16 miles, and printed in dot and dash on the Morse ribbon. The number of words per minute transmitted has not been very great when compared with the speed of the ordinary line, but there are many exceptional circumstances in which that drawback may be more than counterbalanced by the several advantages of the Marconi system.

One thing, however, the Marconi system has yet failed to do, that is, to transmit messages which will only be recorded by a single selected receiver. In the early days of the Marconi system there was much talk about this being done, by taking advantage of the principle of resonance; but it has been found that in practice this principle cannot be utilized by the Marconi apparatus. The theoretical conditions under which synchronism or syntony can be made effective in telegraphy by electric waves have been thoroughly investigated by Dr. Lodge, and the results of his investigations have been embodied in practical form in a system of apparatus which has already been explained in general terms, but which we are now able to describe in greater detail.

In Lodge's invention the method of intercommunication consists in utilizing certain processes and apparatus for the purpose of producing and detecting a sufficiently prolonged series of rapid electric oscillations, and in so arranging them that the excitation of a particular frequency of oscillation at the sending station may cause a telegraphic instrument to respond at a distant station, by reason of being associated through a relay with a subsidiary circuit capable of electric oscillations of that same particular frequency, or of some multiple or submultiple of that frequency. Other distant stations will similarly be caused to receive messages by exciting at the sending station alternations of different frequency. Individual messages can thus be transmitted to individual stations without disturbing the receiving appliances at other stations which are tuned, timed, or syntonized to a different frequency. Each station is usually provided with both sending and receiving apparatus.

A complete system of Hertzian wave telegraphy may be said to consist, in its simplest form, of an arrangement shown diagrammatically in Fig. 1, where A represents the emitting apparatus, and B the receiving apparatus. In the emitter illustrated in Fig. 1, electricity from a suitable source, such as

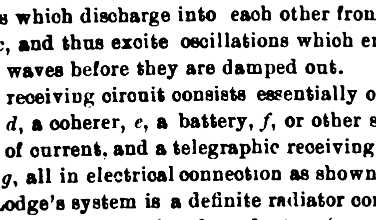

FIG. 1.

a Ruhmkorff coil, a, is supplied to a pair of conductors which discharge into each other from knobs b and c, and thus excite oscillations which emit one or two waves before they are damped out.

The receiving circuit consists essentially of a collector, d, a coherer, e, a battery, f, or other suitable source of current, and a telegraphic receiving instrument, g, all in electrical connection as shown.

In Lodge's system is a definite radiator consisting of a conductor or a pair of conductors (represented by the letters h h^1 in Fig. 2 and following figures). These conductors are of large capacity and may be arranged either as a Leyden jar, or preferably spread out separately in space (one of them being the earth when desired). To h and h^1 respectively are joined a pair of polished knobs h^2 h^3 (protected by glass from ultra-violet light), which form the adjustable spark gap called the "discharge gap." Between either capacity area and its knob is placed a self-inductance coil, i.e., a coil of wire or metallic ribbon, h^4, preferably insulated with any solid or fluid insulator, as in Fig. 2, or in air, and of a shape suitable to attain the greatest inductance with a given amount of resistance. The object of this coil is to prolong the electric oscillations occurring in the radiator, and so constitute a radiator of definite frequency or pitch, emitting a succession of true waves. This renders syntony in a receiver possible, because the exactitude of the response depends on the fact that the total number of oscillations in a suitably-arranged circuit is very great, so that a very feeble impulse is gradually strengthened till it causes a perceptible effect, on the well-known principle of sympathetic resonance.

The electricity is supplied to the radiator by a Ruhmkorff coil, a Tesla coil or an influence machine, in one of three different ways according to circumstances.

The first way is by leading wires from the machine to the two discharge knobs, h^2 h^3, which gives a discharge which follows on a fairly steady electric strain.

The second way consists, as shown in Fig. 3, in having a supplementary pair of spark gaps, h^6 h^7 (which are called "supply gaps"), one knob of each (called the receiving knob) being attached to the middle or other convenient point of each capacity area, h h^1, and the other knob of each pair (called the supply knob) being connected by wires, h^8, to the Ruhmkorff coil a, and brought moderately near the first, so that when the coil is in action the capacity areas shall receive their positive and negative charges by aerial disruption, that is, in a sudden manner, rather than by the slower process of metallic conduction. They are then left to discharge into each other through the connecting coil, h^4, and across the short spark gap between the knobs h^2 h^3. The best width of this gap depends on circumstances, and it may be closed altogether without stopping the action. The gap between the knobs h^2 h^3 may, if desired, be closed by a shunt, h^9.

On the third plan, as indicated in Fig. 4, a Leyden jar or other suitable condenser, j, is intercalated in each of the wires, h^8, leading from the coil, a, to the supply knobs, so that the knobs are supplied from the outer, that is, the uninsulated coat of each jar, while between the inner coats or coil terminals a third spark gap, called the starting gap, also consisting of two knobs, h^{10} h^{11}, is arranged. The outer coats of the jars must not be insulated from each other; they are usually joined by a self-inductance coil of fairly thin wire, k, so as to permit thorough charging. When the discharge occurs, this wire acts as an alternative path, but on account of its self-inductance does not prevent the sparks at the supply gaps.

By both the methods described with reference to Figs. 3 and 4, the two capacity areas, h h^1, which, together, with the inductance coil between them constitute the radiator or aerial disruption or impulsive rush, are charged. The advantage obtained is that charges so communicated are left to oscillate free from any disturbance due to maintained connection with the source of electricity, and therefore oscillate longer and more simply than when supplied by wires in the usual way. Moreover, the capacity areas of the radiator are thus more conveniently employed as the capacity areas of a receiver without need of disconnection.

The arrangement described with reference to Fig. 4 illustrates most completely the method of charging the capacity areas, h h^1, with an impulsive rush.

The action is as follows: The Ruhmkorff coil a charges the jars j, whose outer coats are connected, and discharges them at the starting gap, h^{10}. This spark precipitates a discharge at the supply gaps, h^7 h^8, and suddenly supplies the capacity areas, h h^1, with electric charges, which then surge through the connecting coil, h^4 (divided into two parts in this figure), and spark into each other at the discharge gap between the knobs, h^2, h^3. This last discharge is the chief agent in starting oscillations which are the cause of the emitted waves. But it is permissible in the arrangements, Figs. 3 and 4, to close this last gap when desired, and so leave the oscillations to be started by the sparks at the supply gaps alone, their knobs, in that case, being polished and protected from ultra violet light, so as to supply the electric charge in as sudden a manner as possible.

Spheres or square plates, or any other metal surfaces may be employed as capacity areas, but for the purpose of combining low resistance with great electrostatic capacity, Lodge prefers cones or triangles, or other diverging surfaces, with vortices adjoining, and their larger areas spreading out into space. A single insulated surface may be used in conjunction with the earth, the earth or conductors embedded therein constituting the other oppositely

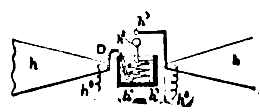

FIG. 2.

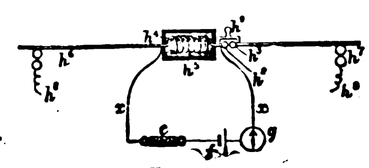

FIG. 3.

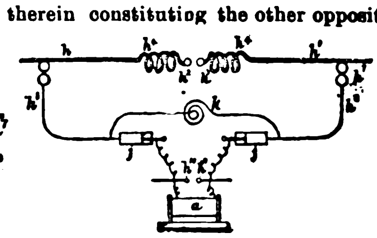

FIG. 4.

charged surface. Radiation from an oscillator consisting of a pair of capacity areas is greater in the equatorial than in the axial direction, and, accordingly, when sending in all directions is desired, it is well to arrange the axis of the emitter vertical. Moreover, radiation polarized in a horizontal plane, that is, with its electric oscillations vertical, is less likely to be absorbed during its passage over partially conducting earth or water. A pair of insulated capacity areas arranged for long distance signaling is shown on the left-hand side of Fig. 5.

Fig. 6 shows a single insulated capacity area, h, with the earth acting as the other surface, and leading up to the spark knobs, h^2, h^3, by a triangular sheet or cone, h^1, so as to afford good conductors even to rapidly alternating currents. The wire, h^8, in this case leads to one terminal of the Ruhmkorff coil, r, the other terminal of which is taken to earth. The capacity area, h, is insulated as shown at h^{12}.

Fig. 7 shows an arrangement which will catch the wind less, and which is fitted with a syntonized coil, h^4.

Fig. 8 shows an insulated metal surface, in the form of a roof, h, of a shed or building, which may be used as a capacity area, suitable connection and apparatus (not shown) for emitting or receiving being placed inside the little house, l.

The self-induction coil, represented at h^4 in all the figures, is a coil of highly conducting wire or ribbon, well insulated by air or by some other medium, as already described, or else covered to a sufficient thickness with insulating material. It may be either a flat coil, enclosing a plane area and shaped so as to have a maximum self-inductance for a given resistance, or it may be a cylindrical coil wound on a finely subdivided iron core, as shown at m, Fig. 9, either ring-shaped, or U-shaped, or straight.

The discharge knobs, h^2, h^3, may be arranged at one end of such a coil as shown in Figs. 2, 3, 7 and

* From the *Electrical Review*, London.

9, or the coil may be in two halves, with knobs inserted in the middle at pleasure.

Several such coils, h^4, h^{4x}, h^{4xx}, with their knobs, h^3, h^{3x}, h^{3xx}, may, as shown in Fig. 10, be arranged for use with a single pair of capacity areas, and any one of them may be brought into action by a suitable switch. Thus the desired frequency of vibration or syntony with a particular distant station may be attained by replacing one coil by another, for the frequency can be adjusted either by varying the capacity of the condenser or jar or other conductor employed, or the charged body, or, on the other

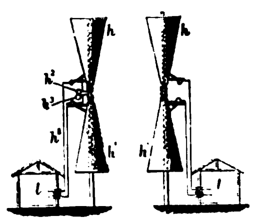

FIG. 5.

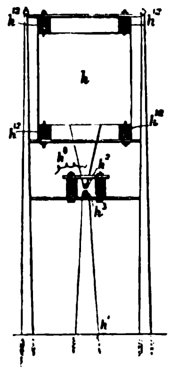

FIG. 6.

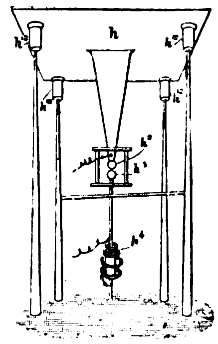

FIG. 7.

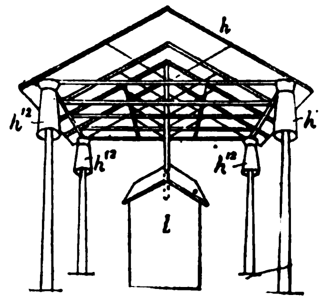

FIG. 8.

hand, by varying the number and position of coils or other portion of the discharge circuit. That discharger is in action whose spark gap is allowed to operate, and a switch, A^1, B^1, C^1, can determine which of a set of different coils shall be utilized. Fig. 11 illustrates the form of switch indicated at Fig. 10.

An alternative plan to that described in Fig. 10 is to connect the capacity areas through one pair of knobs and a single large coil of a considerable number of turns, as shown in Fig. 9, and to have keys or plugs or switches, S^1 and S^2, whereby some of the turns can be shunted out of action, so that the whole or any smaller portion of the inductance available may be used, in accordance with the correspondingly tuned receiver at the particular station to which it is desired to signal. This arrangement may be used in lieu of, or in combination with, interchangeable inductance coils such as are shown in Fig. 10; in the latter case they are useful for correcting slight errors in tuning for any one station.

Another plan, and one well adapted to secure accurate tuning, is to arrange some or the whole of a syntonizing coil so that its parts may be made to approach or recede from one another. The one is named by Lodge an adjustable coil, and the others replaceable or interchangeable coils.

A receiver or resonator consists of a similar pair of capacity areas connected by similarly shaped conductor or self-inductance coil, the whole constituting an absorber arranged so as to have precisely the same natural frequency of electrical vibration as the radi-

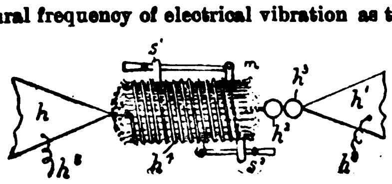

FIG. 9.

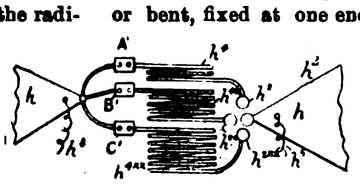

FIG. 10.

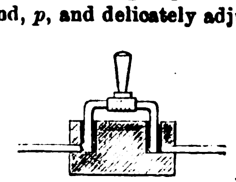

FIG. 11.

ator in use at the corresponding emitting station; but it must not have a spark gap such as h^2, h^3, or if it have a spark gap the same must be carefully closed or shunted, or bridged across by a good short conductor, for example like Fig. 11, before the arrangement can be properly used as a receiver.

Referring to Fig. 3, it will be seen that that diagram illustrates a combined emitting and receiving apparatus. When in use as a radiator, the gap between the discharge knobs, h^2, h^3, is left open. When utilized as a resonator, the said gap is closed by the shunt, h^9 (shown on a larger scale, Fig. 11), and the coherer, c, battery, f, telegraphic receiving instrument, g, are connected through a thin wire, x, from each end of the inductance coil, h (i. e., from each of the capacity areas).

If the Ruhmkorff coil, a, had been actually connected to the capacity areas, h h^1, as in Fig. 2, then it must be detached and substituted by the coherer circuit when a receiver is required; but if the charge has been supplied through gaps as in Figs. 3 and 4 (and this is the best plan), then the Ruhmkorff connection can be left unaltered, as it in no way then affects the action of the resonator, provided always that the coil is not put in action while the receiving circuit is connected up.

A coherer consists of any arrangement which drops in resistance on receipt of an electric impulse, and rises to its old resistance on being subjected to a mechanical impulse, such as a tremor or tap.

A coherer circuit is any known arrangement for observing or recording effects due to fluctuations in the electrical resistance of a coherer.

Lodge makes use of Branly's coherer, in which a pair of conductors are embedded in metallic grains or powder or filings. He prefers to use selected iron filings of uniform size, sealed up in a good vacuum, and with communicating surfaces or electrodes reduced to points of thin platinum wires fused into the glass with their ends close together. Instead of

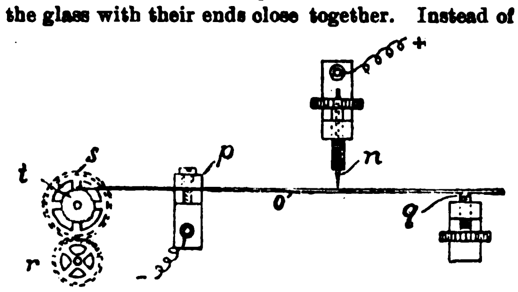

FIG. 12.

the Branly or other well-known coherer, Dr. Lodge also makes use of the coherer illustrated, Fig. 12, wherein a point, n, rests lightly on a flat metallic surface, o. For instance, a needle point of steel or platinum may make light contact with steel or aluminum or other spring like a watch spring, straight or bent, fixed at one end, p, and delicately adjustable by a thumbscrew, q, at some other part, so as to regulate the pressure which it exerts on the fixed needle point.

Whenever an electric wave or impulse from a distant radiator arrives and stimulates electric vibrations in the syntonized resonator or absorber arranged for the purpose, the delicately-adjusted junction of the two metals, or of the metallic or other particles which are connected up to the resonator so as to feel these vibrations, suddenly and greatly changes its electrical resistance, and this diminution of resistance enables a local battery to actuate a relay or a telephone or other telegraphic instrument in circuit therewith.

To break contact again, or to restore the original resistance, any form of mechanical vibration suffices. Lodge mounts on the stand of the coherer either a clock or a tuning fork, or a cog-wheel, or other device for causing a shake or a tremor of sufficient intensity, maintaining it in motion by either a spring or weight, or by electrical means. In Fig. 12, r and s are two wheels of a clockwork train. Upon the arbor (or on a disk mounted thereon) is a series of serrations or the like, t (shown exaggerated in the drawing), which as the wheel rotates effects the vibration of the lever or spring, o. Such a tapper as is used in dentistry likewise serves very well, or the mere motion of any clockwork attached to the stand will suffice. An exceedingly slight, almost imperceptible tremor is all that is usually needed.

The diminution of resistance takes place instantaneously, and contact is broken again in a very small fraction of a second later. The instant it is broken the junction is ready to receive a fresh signal. The rapidity of signaling depends on the quickness of response of the signaling instrument, and it depends also on the rapidity with which the mechanical arrangement can break or interrupt the cohesion directly after the electrical stimulus has established it. Lodge has found that when a telephone is used the coherer restores itself without specially arranged tremor, and that a telephone is the quickest responder that can be used.

In the coherer circuit the coherer is usually ar-

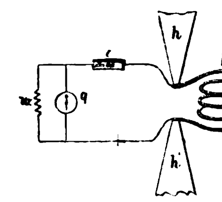

FIG. 13.

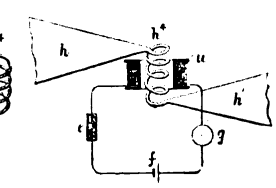

FIG. 14.

ranged with the coherer in simple series with a battery (voltaic or thermal) and a galvanometer or other indicator or recorder of fluctuations of current. The terminals of this series of instruments are then connected to the capacity areas of the receiver close to its self-inductance coil, so that this same coil of wire completes and forms an essential part of the coherer circuit. The coherer is thus affected by every electrical disturbance occurring in the connecting coil or in its capacity areas, and by the aid of the battery at once enables the telegraphic or telephonic instrument to appreciate and indicate the signals. This plan is shown in Fig. 13. It is an improvement on any mode of connection that has previously been possible without the connecting coil.

In some cases Lodge, as shown in Fig. 14, surrounds the syntonizing coil of the resonator with another or secondary coil, u (constituting a species of transformer), and makes this latter coil part of the coherer circuit, so that it shall be secondarily affected by the alternating currents excited in the conductor of the resonator. The coherer is thus stimulated by the currents in the secondary coil, and not primarily by the currents in the syntonizing coil itself, the object being to leave the resonator freer to vibrate electrically without disturbance from attached wires.

In all cases it is permissible and sometimes desirable to shunt the coils of the telegraphic instrument by means of a fine wire or other non-inductive resistance, as shown at w in Fig. 13, in order to connect the coherer more effectively and closely to the capacity areas or receiving arrangement whereby it is stimulated.

Dr. Lodge has not yet published the results of any experiments in which distances have been traversed by means of his signaling apparatus as great as those that have been attained by the Marconi system. A few months ago he informed us that he had transmitted signals over a distance of one mile without any perceptible falling off in the efficiency of the

apparatus. This points to much better results being achieved. The utilization of resonance would appear to indicate that the inconvenience of the long vertical conductor in the Marconi apparatus may be altogether got rid of. The results of further experiments with Lodge's apparatus will be eagerly looked for by those interested in this subject.

THE WERNER LEAD-ZINC-CADMIUM STORAGE BATTERY.*

One of the most interesting modifications of the lead accumulator, but one which has not yet given adequate industrial results, is the lead-zinc accumulator. It was at first studied by d'Arsonval and Carpentier and subsequently improved by Reynier. In this cell the acidulated water is replaced by a sulphate of zinc solution, and the negative plates by sheets of smooth lead or of zinc. The positive plates are of lead, either of the Planté or Faure type. During charge zinc is deposited on the negative electrode and the positive is peroxidized. During discharge the zinc dissolves and the positive plate is reduced to a state of inferior oxidation. This combination offers two advantages over the ordinary lead accumulator: (1) The mean electromotive force of discharge is from 0.3 to 0.4 volt higher. (2) The "specific capacity" is greater on account of the diminution in weight of the negative electrodes. On the other hand, it is difficult in this type of accumulator to ensure a good and solid metallic deposit on the negatives; and, moreover, the zinc which has been deposited dissolves on open circuit, with an evolution of hydrogen, causing the cell to lose its charge rapidly. To stop this local action Reynier reduced the surface of the negative electrodes as much as possible and amalgamated the zinc.

The special feature of the Werner accumulator is the composition of its electrolyte, which is a solution of a mixture of sulphates of zinc, cadmium and magnesium. During the charge a deposition of zinc and cadimum takes place, and at the same time a certain quantity of hydrogen is produced, which combines chemically with these two metals. During discharge this deposit is dissolved, and the useful limits of potential difference are 2.3 and 1.9 volts. As already mentioned, it is necessary, for the realization of a good accumulator with metallic sulphates, to obtain a good and hard metallic deposit on the negative plates, which does not get used up on open circuit. M. Werner has found that a second condition must be added, a condition in many cases contradictory to the first—that a good peroxidation of the positive plates be obtained, the peroxide of lead possessing a high degree of what M. Werner calls "molecular permeability"—a thing not to be confounded with internal resistance. When a well-formed mass of peroxide is being discharged the particles close to the grid are used up more than the remainder of the material. Gradually, however, an inter-molecular action takes place, which tends to restore the homogeneity of the material. Now it is observed that for the same positive plate and the same electrolyte resistance this inter-molecular action characterizing the "molecular permeability" is more or less rapid according to the composition of the bath and its temperature. The two conditions mentioned above are contradictory, because, to obtain a good deposit on the negative plate, a very concentrated bath is necessary, but when the bath is concentrated the "molecular permeability" becomes insufficient, this being shown by the rapid fall in the potential difference between the terminals of the cell—the cell becomes "fatigued" too quickly. For example, with a concentrated bath of zinc sulphate hardly any peroxide is formed on the positives. With a bath of concentrated sulphate of cadmium peroxide is certainly formed, but the useful potential difference, which is 2.4 at the commencement of the discharge, falls to 1.8 volts when only 10 per cent. of the total charge has been utilized. After a rest of a quarter of an hour, the discharge can be resumed at 2.1 volts. M. Werner found that, in presence of sulphate of magnesium, the deposit of zinc and cadmium is very regular, even in a weak bath; at the same time the molecular permeability of the positive plate is considerably increased.

M. Werner constructs two types of negative plates: one for relatively low discharge rates, the other for rapid discharges. For instance, for a discharge in six hours, which is required for electric carriages, the negatives are made of very thin sheet iron covered previously, by immersion, with a layer of lead. As the concentration of the bath diminishes gradually as the cell charges, it is useful to diminish the charging current also. This occurs automatically when the cell is charged at constant potential, and this is the treatment preferred. At the commencement of the charge the zinc-cadmium deposit is crystalline with a fine texture; towards the end it becomes amorphous, less hard and more spongy. The charge is stopped when 60 per cent. of the salts has been decomposed. The waste on open circuit depends on the nature of the bath and on the quality of the deposit. When cadmium is predominant in the bath, so that an initial electromotive force of 2.4 to 2.48 volts is obtained, the waste on open circuit would be very small and would not exceed 3 per cent. of the total deposit per diem. It may be mentioned that it is only the negative plate that wastes on open circuit, so that if by overcharging a deposit is produced on this plate more than sufficient for the positives, the waste on open circuit only diminishes the efficiency and hardly diminishes the capacity.

For rapid discharge accumulators another type of negatives is used. In this case it is impossible to employ a concentrated bath, but with a weak bath a very spongy deposit is obtained, and a considerable quantity of hydrogen, whose escape it is of advantage to prevent. This has led to the construction of plates made of a very thin and light grid, covered with a paste of lead and spongy cadmium, the whole being submitted to great pressure. In this manner plates are obtained which are at the same time strong and light and which receive the metallic deposit and the hydrogen in their pores. The waste on open circuit is practically *nil*. These plates have been especially employed in accumulators for lighting trains, where they have to be charged and discharged in 2½ hours.

For the positive electrodes two things have to be considered: the weight of active material and the surface of adhesion of this material to the support. The total capacity of a positive plate only depends on the weight of active material, but the useful capacity decreases as the discharge-rate increases, but this decrease is less the greater the surface of adhesion between the material and its support. Whatever the conductivity of the active material, the portions in contact with the grid are exhausted quicker than the remainder, and the difference of potential at the terminals falls to below the useful limits before all the active material is exhausted. It appears useless, therefore, to increase the weight of the active material when the surface of adhesion is not great enough. According to M. Werner the insufficiency of this surface is the principal cause of the premature destruction of the positive plates. It is known, in fact, that of all the oxides of lead the peroxide alone is not attacked by sulphuric acid. With a small surface of adhesion, parts adhering to the grid are completely discharged and pass to the state of inferior oxides which are easily sulphated. This is why a white layer of lead sulphate is always found when an old oxide positive plate is broken. Guided by the above considerations, M. Werner tried to increase the surface rather than the quantity of active material supported by the grid. The positive plate is formed of a strong grid with wide pastilles (4 by 5 cm.). On the two sides of the grid are soldered, upon a stay, two or four thin sheets of lead wire-work, resembling metallic cloth. The whole is subjected to a Planté forming, so that a layer of peroxide 1 mm. thick is obtained. The grid is then filled with lead peroxide paste and minium and is subjected to a very great pressure. Thus a mass is obtained which is traversed everywhere by lead wires. These positives are strong and of large capacity and they have nothing to fear from rapid discharges.

The Werner lead-zinc-cadmium cell gives, according to the inventor's figures, 37.2 watt-hours per pound of plates when discharged at 12 to 15 amperes, corresponding to 16.3 watt-hours per pound of cell complete. It is stated that an electric carriage fitted with these cells has been running in London for some time past. This carriage has a battery weighing 737 lbs., consisting of 30 cells of 180 ampere-hours' capacity at 30 amperes discharge.

* Abstract of an article from *L'Industrie Electrique* in *Electrician*, London.

VIEWS OF THE SCIENTISTS.*

The Magnetic Deflection of Diffusely Reflected Cathode Rays.

By Ernest Merritt.

It is not known that X-rays are developed in a Crookes tube at all places where the cathode rays encounter a solid obstacle. In the tubes now made the cathode rays are usually "focused" on a piece of sheet platinum, and the X-rays proceed from this focus. But other rays are developed at this point as well as Roentgen rays and are the cause of the brilliant fluorescence which usually covers about half the glass of such tubes. These rays are deflected by a magnet like cathode rays; in this they differ from X-rays, which are entirely unaffected by the most powerful magnetic field. Goldstein, who first observed these rays, believed them to be cathode rays that had been diffusely reflected from the platinum, just as light would be scattered by a roughened surface. S. P. Thompson believed that the rays were intermediate between cathode rays and X-rays, and has proposed for them the name "para-cathodic rays." The author has measured the deflection o the "para-cathodic rays" in a given magnetic field and compared it with the magnetic deflection of the direct cathode rays in the same tube. No difference could be detected in the behavior of the two sets o rays. This fact must be looked upon as an argument in favor of Goldstein's view. According to the generally accepted theory cathode rays consist of small negatively charged particles repelled at enormous speed from the cathode. It seems probable that when these particles strike an obstacle some are stopped and by their impact produce the X-rays; a few of the particles may, however, rebound like elastic balls. The particles that rebound will then travel off with practically undiminished velocity and will form the "para-cathodic rays," possessing all the properties of the original cathode rays. The author is therefore of the opinion that "para-cathodic rays" are really the same as cathode rays, and result from diffuse reflection.

Methods of Determining the Frequency of Alternating Currents.

By Carl Kinsley.

We have all noticed the hum of a transformer or alternating current arc light machine. Upon the pitch of that note depends in a great measure the current of electricity that exists in the wire. It is consequently of importance to electricians to determine the frequency of the alternations which produces the low note in electrical apparatus. If the

* Abstracts of Papers read at the recent Convention at Boston of the American Association for the Advancement of Science.

current flows through an electro-magnet it will turn it into a pulsating magnet which will make a piano wire, tightly stretched, vibrate as though it had been struck. From the force used to stretch the wire, the rate of vibration of the wire and consequently of the alternating current can be calculated.

The same thing occurs when an iron strip is held in front of the magnet. Upon the length of the strip depends the rate of vibration, and that is easily calculated from the strip itself. Dr. John Hopkinson first used the piano wire and Dr. Campbell the iron strip.

Another way is to have a little of the electricity flow through a telephone receiver. The hum of the telephone will show just how fast the current is alternating. This rate of vibration can be measured by making the air in a long tube vibrate in unison with the telephone. It is merely necessary to measure the length of the tube in order to compute how fast the current is alternating. This method is capable of great rapidity of operation and accuracy in getting the result.

Still another method, which can be most easily used of all of them, consists in varying the rate or vibration of a metal strip, not by changing the length, but by hanging weights on the bar. Or else one weight may be used and its distance from the end of the bar varied. When the electrical current passes through the magnet the weight is moved until the bar vibrates. Then the position of the weight will tell the experimenter how many times a second the bar vibrates and consequently how many alternations per second the alternating current has.

On the Electrical Properties of the Vapors from the Carbon Arc.

By Ernest Merritt and O. M. Stewart.

The air, as well as other gases, is usually a non-conductor except when at a very high temperature. The gases from a flame, however, are to some extent conductors of electricity. They possess the power, for example, of discharging an electrified body with which they come in contact. Other gases acquire this discharging power when acted on by X-rays and retain it for a fraction of a second. The authors find that the vapors from an arc light behave in almost exactly the same way as do gases which have been acted on by X-rays, except that they retain their discharging power longer. If the vapors are drawn from the arc through glass or metal tubes, and caused to pass between a charged body and one that is grounded, the former will gradually lose its charge. The discharge current is however not proportional to the potential difference, but increases less rapidly than the latter and approaches a limiting value. If the vapor of water is introduced into the arc the rate of discharge is greatly increased. All the phenomena observed may be explained upon the assumption that the air is "ionized" by passing through the arc, i. e., the molecules of air are to some extent torn apart so as to form positive and negative ions as in electrolysis. These ions rapidly recombine, and their number being limited the maximum current that can be carried by the vapor is relatively small.

The experiments probably have an important bearing upon the theory of conduction in the electric arc.

The Contact Resistance of Similar Metals.

About three years ago, says the *Electrician*, London, M. Edouard Branly, while experimenting on the contact resistance of dissimilar metals, found that for some metals and alloys (copper, zinc, brass, silver, german-silver, etc.) the contact resistance had a very small value, whereas for others (iron, aluminum, lead, bismuth, etc.) the value was unexpectedly high under certain conditions. In the *Comptes Rendus*, of July 25 last, he describes experiments made with similar instead of with dissimilar metals. A column, outwardly resembling a Volta pile, was made by threading 45 disks, 35 cm. diameter and 6 mm. thick, of the metal under test on an ebonite rod and submitting the column to a slight pressure. In the case of aluminum, iron and bismuth the resistance was low if the disks were placed on one another gently; but if dropped on one another with a slight shock and subjected to the same pressure as before, the value of the resistance increased enormously. With disks of zinc, copper or brass, on the other hand, the resistance was practically zero however the column was put together. The following figures show the order of the phenomenon: A column of aluminum disks gently placed on one another, and subjected to 2.6 kilograms pressure, had a resistance of 1.5 ohms. By dropping the disks on one another, and subjecting the column to the same pressure, the resistance was 40 ohms, diminishing to 19 ohms after 24 hours. On taking the column to pieces and remaking it gently, but without cleaning the disks, the resistance was 2.2 ohms, and when again remade by dropping the disks upon one another, the resistance was as high as 215 ohms. Connecting the column between the spark terminals of a radiator reduced the resistance to 0.5 ohm. The same effect was noticeable with iron and bismuth, but in a slightly less degree. No attempt is made to account for the phenomenon.

New Blood Circulation Theory.

There is a new and interesting theory of the circulation of the blood put forth by Dr. M. J. Rodermund of Wisconsin. Dr. Rodermund believes the blood is driven through the arteries and veins by the oxygen in the lungs and not by the muscular contraction of the heart. Instead of the blood carrying the oxygen through the system he thinks it is the oxygen that carries the blood, thus exactly reversing the theory held by physiologists since Harvey's discovery of the circulation of the blood three centuries ago. The Wisconsin physician at least makes out a plausible argument for his new theory, and the article in question is likely to set the doctors and physiologists of the scientific world to thinking and talking.

Dr. Rodermund boldly challenges the generally accepted doctrine that the heart acts as a force pump. He says that the heart is merely the automatic "governor" on the engine to keep the pump from working too fast, and that the real motive power of the blood is the oxygen of the air, acting by electrical energy. It is a well-known law in physics that all positive electric bodies repel each other, while negative and positive bodies attract each other. Dr. Rodermund holds that the oxygen in the air cells of the lungs charges the blood corpuscles with positive electricity, which causes them to be driven violently away through the arteries, and furnishes them with force necessary to make their way through the network of tiny capillaries throughout the body. The moment they have gotten through and have had the oxygen absorbed out of them by the muscles and organs they become negative electrically and begin to be attracted back to the lungs through the veins. As soon as they get back into contact with the inflated air cells they are recharged from the fresh air in the lungs and the process is repeated. Thus Dr. Rodermund would have us believe the diaphragm and the lungs are the machine of perpetual motion called life, and not the heart, as generally supposed.

In support of his theory, the Wisconsin doctor urges that it would be impossible for so small an organ as the heart to do the enormous work ascribed to it. He has calculated that the task of driving the blood through the hair-like tubes of the circulatory system is equivalent to raising 200,000 pounds a foot high every hour, night and day. This would mean that the heart raises the equivalent of its own weight 20,000 feet every hour through a lifetime—which Dr. Rodermund thinks is impossible and preposterous. He thinks it is the electrical energy in the atmosphere that does this work, and cites the effect of holding one's breath and other similar experiments to prove that the lungs are the organ of life and the heart only a minor attachment.

WELSBACH'S NEW ELECTRIC INCANDESCENT LAMPS.*

There have been many rumors afloat of late respecting the latest inventions of Dr. Auer von Welsbach, which are directed toward the improvement of the electric glow lamp in respect both of duration of service and light efficiency. In both these directions it must be admitted there is room for substantial betterment, and Dr. Welsbach will deserve well of the public and will reap a substantial reward should he succeed in realizing the expectations he has raised.

The publication of certain patents recently granted to Dr. Welsbach suffices to give a general outline of the direction in which he is working.

The patents here alluded to describe two kinds of glow-bodies for use in incandescent electric lamps. The first is a fine filament of osmium of a peculiar form. Osmium is one of the metals of the platinum group, generally found in nature in the form of flat irregular grains, associated with iridium in the mineral called osmiridium. It may be obtained in the pure state by a chemical method of separation, in which advantage is taken of the fact that the tetroxide, which is readily formed by heating the metal in the air, is a volatile compound. It must be prepared, however, with great care, because of the extremely poisonous character of its fumes.

The second glow-body described is one formed of "thoria," an earth-metal oxide which is already largely employed in the preparation of the well-known Welsbach incandescent gas mantles.

Referring to the osmium filament, the basis of its selection as the substitute for the carbon filament is the claim made by the inventor that it does not volatilize at the highest attainable temperature when confined in a vacuum or surrounded by a reducing atmosphere.

A serious difficulty with the carbon filament in the ordinary electric glow-lamp is the rapid darkening of the glass by the deposit on the inner surface of the glass bulb of carbon, volatilized by the heat of the current, or mechanically worn off by its passage. From this cause the light emission of the common electric glow-lamps is rapidly reduced and it occasionally happens that they must be discarded long before the filament itself is broken. It is principally to avoid this defect of the carbon filament that Welsbach has had recourse to osmium. The present difficulties attending the production of his osmium filaments, however, are so great that it appears gravely doubtful if the method can be made commercially valuable.

The fact that it is impracticable to fuse osmium (and on this great infusibility its value for Welsbach's purpose depends) makes it impossible to obtain it in any other form than that of a powder which cannot be united into a solid mass by pressure and then drawn into wire. It becomes necessary then to obtain the osmium filament by indirect means, and for this purpose Welsbach deposits it on a fine platinum wire maintained in an atmosphere of hydro-carbon vapor mingled with water vapor (*sic*); and the platinum wire being heated to incandescence in this atmosphere by the electric current, small quantities of the vapors of osmium tetroxide are blown in from time to time. The result is that a thin layer of metallic osmium is deposited on the platinum wire. This operation, it would seem from the published account, is a slow and exceedingly delicate one, for the deposited film must be quite uniform to answer the purpose, since any irregularity

*From the Journal of the Franklin Institute.

in the deposit would affect the uniformity of its resistance and yield a light more brilliant in spots. Another method of obtaining the deposit is described, which consists in drawing the fine platinum wire through the solution of an osmium salt and then glowing it in a vacuum. To obtain the film in the required condition, by this method, only an infinitely thick layer must be formed at a single operation, so that it must be repeated many times (100 times at least) to obtain the needful uniformity in the superposed layers. Neither of these methods, therefore, seems to present much promise of success on the commercial scale.

A more practical method suggested is to use vegetable or animal fibers as the foundation for the osmium coating. A liquid pulp is made by mixing the finely comminuted osmium oxide and the fibers with sugar solution or other organic cementing material, and, after drying and cutting into the required shape for the lamp, it is glowed slightly in an atmosphere of reducing gas. By this and slightly modified methods a carbon skeleton is formed carrying a certain quantity of unconsolidated osmium. These methods appear practical, but it will be observed that the resulting filament is not a pure osmium filament, but one consisting largely of carbon, and hence open to the same objections as the common carbon incandescent lamps, besides being vastly more costly.

The second proposal of Welsbach is the thoria filament.

This substance, as above remarked, is one of the rare earths largely used in the manufacture of the Welsbach gas mantles, and is known to possess light-emitting qualities of a high order.

To obtain this filament the inventor employs an extremely thin platinum wire (0.02 millimeters in diameter) approximately as thin as a single fiber of the silk cocoon, and draws this successively through elastic cheeks which are kept moistened with a solution of salt of thorium. After each drawing the wire is glowed, and the operation must be repeated, as in the one above described, many times, in order that the resulting coating may have the necessary permanency.

The resulting thread then is a platinum core, surrounded by a dense incrustation of thoria. The heat-resisting qualities of the incrusting oxide are said to be so great that the platinum wire within may be melted without affecting it, while the amount of heat radiated from the brilliantly luminous thoria is comparatively small. With the current intensity employed for ordinary illumination, however, the platinum core is not melted, the explanation being that the greater part of the heat energy imparted to the platinum is transformed by the fireproof encrusting material into light; the intense power of the coating to emit light withdraws and transforms much of the heat of the metallic conductor into light.

The above description gives merely an outline of the several methods set forth in Welsbach's recent patents. In view of the great expectations raised by the reports of his remarkable laboratory work, it must be confessed that the outcome is a disappointment. While the methods proposed are ingenious, they seem to be altogether too delicate to be capable of being commercially applied, and they are undoubtedly so costly as to place serious competition with the cheap electric glow lamp, with which we are familiar, out of the question.

Electrical Ash Hoists and Deck Drills.

A company in Woolwich, England, is said to have recently introduced a new motor-driven ash-hoist which will be of great service to marine engineers and shipowners. There are two side frames of cast iron carrying the small drum on which the rope connected to the ash bucket is raised. The side frames can be fixed to the deck. The spindle of the drum is connected to the motor in the usual way. The same firm are also introducing electric deck drills, which are extremely simple in construction and convenient in application. The smallest of these is for actuating drills up to a diameter of ⅜ in. It is of considerable weight, and the operator applies it by holding it by two handles fastened at the side. The weight of the machine provides the feeding arrangement. There is speed-reducing gear inside the machine for reducing the speed of the motor to the required speed of the drill. The power is transmitted between the motor and the drill by means of flexible gearing. There is a larger drill also with reducing gear, but this is of a larger size, and can work a drill up to 2 in. diameter. The feeding arrangement is by means of a screw and small hand-wheel, or by means of a nut and small lever inserted into a hole in the nut, as in the case of the ratchet brace. There are three speeds to this drill.

THE FIRST ELECTRIC MOTOR CAR.

L. F. Andrews of Des Moines, Iowa, furnishes the Chicago *Record* with the following facts in connection with the origin of the electric motor car. The statement was suggested by a personal mention of Abner C. Goodell, in which it was said of Mr. Goodell that "he worked on the first electric motor ever constructed, which afterward ran between Baltimore and Washington." Mr. Andrews says:

"The electric motor here referred to was the invention of Prof. George C. Page, tested in 1851. It was a failure in practical results and was abandoned, yet it demonstrated the fact that a speed of nineteen miles an hour could be secured with a locomotive built upon his principle.

"It was not until 1877, in San Francisco, that a railway was electrically operated, and that was by Stephen D. Field. It was his pattern of locomotives that was so successfully operated during the Columbian Exposition in Chicago in 1893. Mr. Field simply had perfected and utilized an accidental discovery of reversible dynamic power as made by Gramme of Paris in 1872.

"As a historic fact the first electric motor was the invention of Thomas Davenport, assisted by Orange A. Smalley and Collins Andrews. It was made at Brandon, Rutland county, Vt. Mr. Davenport was only an ordinary blacksmith, going to perform with the force and energy which was wrapped up in 'galvanic magnetism.' He at once began the development of his idea. Ignorant of mechanics, he enlisted the aid of Andrews and Smalley, both practical machinists, and the latter the inventor and maker of an automatic machine for cutting the screw threads of nuts and bolts.

"It was not until 1835, after four years of labor, that a successful motor was completed. The power used was galvano-magnetic. The track was circular and of about eighteen inches gauge, on which a small platform car was run, having a seat for two persons. As I frequently rode upon it, I can safely aver that it was an electric railway.

"In 1847 Moses G. Farmer constructed an electro-magnetic motor on the principles developed by Davenport. His machine was exhibited through the Eastern States. The power was generated from forty-eight pint-cup cells of a Grove battery. The difficulty with the Davenport, Farmer and Page motors was the great cost to run them, and for economic reasons they were abandoned. It was not until the dynamo came that Davenport's thought was completely evolved. Mr. Smalley wrote me a letter a short time before his death, which occurred not long ago. He said: 'Work has been done on the machine since I left it in 1835, but nothing has been added to the principle. Give electricity seventy years, with the talent now available, and there will be no need of overhead wires or underground conductors. Lightning will be made to order sufficient for any purpose.' It is quite pertinent here to say that while Davenport was working out his motor a wire was run between his house and that of Smalley, over which messages were transmitted by electricity."

Coherers.

The actual change which takes place in a coherer when it responds to an electric wave is a matter of great interest to wireless telegraphists. Some Italian physicists succeeded already in demonstrating a cohesion produced in an emulsion of mercury drops in oil. L. Arons has been studying the occurrences in coherers under the microscope. They were prepared by cutting a fine line across a thin strip of tinfoil stuck on glass, laying a little metallic powder over it, adding a drop of Canada balsam, and covering with a cover glass. Thus the whole field of action could be brought within the range of vision. The Canada balsam did not in the least interfere with the efficiency of the coherer, a fact which gives some idea of the energy of the reaction. The newly-prepared coherers had an infinite resistance. On exposure to waves full contact was as a rule immediately produced, especially when the particles were at all dense. Under the microscope violent commotions and a play of sparks were observed among the particles. The green sparks between silver particles were especially bright. Usually the contact may be annulled by tapping. Sometimes, especially in the case of brass filings, one or two particles stick on hard and their surfaces show signs of oxidation. They must then be removed by a brush. When the particles are embedded in Canada balsam a light pressure on the cover glass suffices to annul the conductivity.

A peculiar phenomenon observed is the destruction of contacts by a repetition of the vibrations which produced them. That this does not occur in the usual forms of coherers is probably explained by the fact that the large number of new contacts formed neutralizes the effect of the breakages. In all cases the coherers showed signs of wear after repeated use, especially the embedded coherers. In the latter the liquid was found to contain minute bubbles. On one occasion, when the cut across the tinfoil (0.019 mm. wide) was particularly smooth and straight, the author exposed it to waves without powder. In this case a number of small sparks played across the edges, and the resistance fell to 10^7 ohms. Under the microscope the intervals appeared pretty evenly covered with a fine brown deposit, divided from the tinfoil by a very narrow line. The tinfoil itself appeared somewhat frayed. The brown deposit, which consisted of oxidized tin dust, could be easily taken off with a brush. The importance of this particular experiment, in face of Auerbach's results, lies in the fact that the reaction could hardly have been anything but purely electrical.—*Electrician, London.* [Abstract of paper by Arons, in *Wied. Ann.*, No. 7, 1898.]

Electricity to be Generated on the Nile.

One of the most interesting announcements of the day is that of the assured progress of tapping the river Nile at its higher level above the Cataracts, conducting the water to vertical shafts, down which it will fall to drive turbines, then using the power so generated to run dynamos, from which electricity in the form of alternating or continuous current will be transmitted to points near or remote. The water, after passing through the turbines, will be restored to the river at a lower level or else used to irrigate the land. There will be no waste of material, as in burning coal, and no smoke. Electricity will be applied, not only in pumping for the irrigation, but in driving machinery for preparing the raw products of the soil, spinning cotton, weaving silk and various other industries. But even this surprising scientific scheme is eclipsed by the later proposal, to raise water to an elevation by the sun's rays and use it to run a water wheel and dynamo—the water being

contained in tanks within a structure of glass similar to a conservatory; the sun's heat, expanding the air in the first tank containing water, forces it into the tank above, the air being cooled by screening the tank, and the water then raised to the next tank. The sun's rays acting on a square mile will, it is calculated, furnish one million horsepower, and, with a temperature of fifty degrees in the glass houses outside, the efficiency of the arrangement is elieved to be practicable.

Decomposition of Compounds by Electrical Oscillations.

In some recent experiments by Alexander de Hemptinne, various organic compounds were exposed in the gaseous state, at low pressure, to the influence of electrical oscillations, and the decomposition products were examined. From methylic and ethylic alcohols, mixtures of carbonic oxide, carbonic anhydride, hydrogen and methane of ethane are obtained, and as the quantity of oxides of carbon is diminished if the decomposition occurs in the presence of phosphorus, the author considers these compounds to be due to secondary actions, the primary reaction being represented by CH. OH = CH O; analogous decompositions occur in the cases of propylic, isopropylic and allylic alcohols. With acetone and propaldehyde, however, the presence of phosphorus causes no diminution in the quantity of oxides of carbon; these are hence produced in the primary decomposition, which is in each case CHO = CH CO.

Acetaldehyde undergoes an analogous decomposition, but acetic and propionic acids decompose with the formation of oxygen and the unsaturated hydrocarbon. Methylic acetate and ethylic formate give the same decomposition products, and the chemical formula gives no indication, in the author's opinion, of where the strongest mechanical attraction occurs. A few liquids were also exposed to the oscillatory discharge, and glycerol, glycol, glyoxal, glyceric acid, and oxalic acid were all found to be partially decomposed. Phenol and benzoic acid yielded oxides of carbon and hydrogen, and resinous compounds, the latter, together with hydrogen and acetylene, also being formed from benzene. The above is an abstract in the *Electrical Review*, London, of a paper in the *Zeitschrift für Physikalische Chemie* by Alexander de Hemptinne.

LONDON NOTES.

[From our London Correspondent.]

Bradford Electric Tramways.

These new municipal tramways which have just been opened are supplied with current from the municipal lighting station. Altogether the two sections (Bolton Road and Great Horton) measure from seven to eight miles of single track. They are equipped partly with the side pole system and partly with the center pole. The latest Dawson type of swiveling arm trolley is used. Some of the gradients are 1 in 14, and there are some rather sharp curves. The overhead trolley wire is of .325 inch hard drawn copper. The line is as usual divided into half mile sections which are controlled from feeder switch pillars fitted with six plug switches, test terminals and lightning arrester. The rails, which are 105 lb. girder type, are bonded with Chicago crown flexible bonds, and at 120 ft. intervals cross connection bonds are placed. The car bodies, built by the Brush Electrical Engineering Company, are mounted on Peckham cantilever extension trucks. Each car has two Westinghouse No. 49 slow-speed single reduction motors. The armatures are of the drum type. Westinghouse No. 90 brake series parallel controllers are used, the controllers being so arranged as to utilize the motors for electric brakes. There is a standard platform switch at one end of the car and an automatic switch cut-out at the other end. There is a special tramway switchboard placed in position at the municipal lighting station, where the necessary additional plant for the tramways has been installed. This switchboard stands three or four feet distant from the wall. It has feeder panels, generater panels and the usual Board of Trade test panel. Measuring instruments and an automatic circuit breaker of the Cutter type are fitted to each panel. The principal contractors for the construction and equipment of these tramways were the Westinghouse Electric Company, Ltd., of London. Mr. A. H. Gibbings is the borough electrical engineer.

LEGAL NOTES.

Mrs. Frances A. Henderson has brought suit in the Circuit Court at Newark against the North Jersey Street Railway Company, claiming $25,000 damages. She was riding on an open Elizabeth trolley car on June 1 and dropped her pocketbook. She signalled to the conductor to stop, but before she could fairly get off, the complaint says, the car started up again and she was thrown violently to the ground.

On the 29th ult. at Philadelphia, Henry J. Hartley and twenty-three other stockholders of the Penn Electric Light Company filed a bill in equity in Court No. 2 against the company, J. Lowber Welsh, Thomas Dolan, William Wood, Richard Brock, Clement B. Newbold, George W. Hill, John Boyd and A. J. DeCamp, individually and as trustees of the "Electric Trust of Philadelphia," asking that the defendants be ordered to make discovery in certain transactions and account for profits alleged to have accrued to them. The litigation follows in its general outlines other similar proceedings previously brought. The complainants, as minority stockholders of the Penn Electric Light Company, aver that some of the defendants obtained a controlling interest in the corporation, and used its underground conduits, which were its principal property, in a manner other than for the best interests of the stockholders, by allowing some of them to remain idle and entering into contracts by which the control of the other conduits was given to the Edison Electric Light Company, the Pennsylvania Heat, Light and Power Company and the Pennsylvania Manufacturing Light and Power Company.

The Capital Traction Company of Washington, D. C., on the 27th ult., filed its answer in the suit for infringement on a patent brought recently by the Electric Railway Equipment Company of Virginia. It was alleged that the Capital Traction Company was using a current collector for electric railways which had been patented by one Frederick A. Anderson, who had assigned all of his rights to the complainant company. The answer declares that the Capital Traction Company knows nothing of the complainant and denies that Anderson was the originator or inventor of the apparatus in question. It is also denied that letters patent were lawfully issued to Anderson, the claim being that they are invalid and void. It is alleged further in the answer that the current collectors were manufactured and were in use and on sale in this country two years before Anderson filed application for patent.

THE NEWS.

What is Going On in the Electrical World.

STREET RAILWAYS.

Conneaut, O.—The city council has passed the ordinance granting a franchise to the Pennsylvania & Ohio Railway Company. The proposed street car line will give Conneaut connection with Ashtabula, Geneva, Painesville and Cleveland.

Fostoria, O.—The purchase of the lines and franchise of the Northwestern Ohio Natural Gas Company in this city, and the lines, plant and franchises, gas and electric, of the Fostoria Light & Power Company, for which Samuel R. Bullock, of Philadelphia, has been working since last February, has been consummated. Mr. Bullock is still desirous of securing the belt line belonging to the city and will probably succeed in so doing. It is his intention to put in a gas and electric plant, furnishing both fuel and illuminating gas, municipal, commercial and domestic electric lighting. After the completion of the plant the plant of the Fostoria Light & Power Company will be installed in the new building, giving him a double plant in both lines.

Jackson, Miss.—Gen. S. T. Carnes, to whom a franchise has been granted by the council for an electric light plant and street railway, says that work on the same will begin not later than September 16.

Lawrence, Kan.—The city council has granted a 30-year franchise to the Lawrence Railway Company to build and operate an electric street railway here. The construction of the line is to begin inside of sixty days.

North Tonawanda, N. Y.—George P. Smith of this place, one of the promoters of the Buffalo, Tonawanda & Niagara Falls Electric Railroad, says it is the intention to have a double track road from Buffalo to Niagara Falls in operation by the first of July next year. The road running from Niagara and Tonawanda streets in Buffalo to Tonawanda will be part of the system. To finish the projected line it will be necessary to build 40 miles of track. Mr. Smith says the new railway will run as near the old river road as possible, the directors believing the beautiful scenery along the Niagara will attract passengers. The company has a franchise now to run between Tonawanda and Niagara Falls, and the common council of Niagara Falls has an application before it for permission to allow the road to enter that city.

Plainfield, N. J.—The Brunswick Traction Company, which obtained a franchise some time ago to extend their line from Bound Brook to Dunellen, had to do some hustling to save their franchise. The franchise required that the line should be running by August 30, but the track was not wholly laid on that day, and much of what was laid was covered with earth; the only part that was any way passable was about two miles in that part of Dunellen where it joins the Plainfield trolley tracks. The company had no cars and borrowed an old flat car from the Jersey Central Railroad. This was lifted on the available tracks, a team of horses attached and with the New Market band and the borough council aboard the "line" was started. The two miles were made in two hours, finishing just before the fateful hour of midnight. Part of the time the car was off the track, but all hands turned to and set it on again. The franchise was saved, but it was a close call.

Sedalia, Mo.—The Sedalia Electric Railway and the Sedalia & Brown Springs Railway, purchased on the 26th ult. by Stewart & Co. of New York, will be consolidated under the name of the Sedalia Electric Company. The officers are: S. H. G. Stewart, New York, president; John D. Crawford, Sedalia, vice-president; Carlton H. Reeve, New York, secretary and treasurer. The directors are the above officers and A. C. Zimmerman, New York, and W. H. Powell, Jr., Sedalia.

West Bay City, Mich.—The Business Men's Association has decided to assist the proposed electric railroad to Flint. At least $100,000 worth of patronage is to be assured. A Chicago company will build the road.

LIGHTING PLANTS.

Atlanta, Ga.—At a public meeting held here to discuss municipal affairs a resolution was passed requesting the committee on arrangements for the October primary election to prepare a ballot for the voters on the question "For or against the public ownership of an electric lighting plant."

Atlantic City, N. J.—Mayor Thompson has again vetoed the ordinance granting John H. Rothermel & Co. of Reading, Pa., a five-year franchise for an electric light plant, and the city council has again passed the ordinance over the mayor's veto. Although the ordinance is thus sustained by the council, the Rothermel Company cannot proceed to erect its plant until the actual contract is signed by the mayor. Certiorari proceedings are likely.

Chicago.—Competition between the Edison Company and the Cosmopolitan Electric Company is getting sharp in the 22d district. The "Record" says: "Agents of each concern are canvassing the list of consumers of its rival, and rates are cut freely. The Edison representatives are offering long-term contracts at liberal discounts from their usual monthly rates as an inducement to consumers, while the Cosmopolitan interests advise customers that electric light will be less expensive than terms now offered before the fight is much older."

Fredericksburg, Va.—D. F. Franklin Stakes, electrical engineer of the Fort Wayne Electrical Corporation, is here drawing plans and making estimates for a new electric light plant for the city.

Grand Rapids, Mich.—The board of public works has approved the specifications prepared for the public lighting plant and the secretary has been instructed to advertise for bids. The bids will be opened by the board September 20. The new specifications cover a wide range and are so framed that any firm having any sort or kind of electrical appliances to sell can bid on the same. Bids will be received for the direct connected system as in the old specifications and for the belted system. Bids will also be received for a complete plant, including the power house, arranged according to the idea of the individual bidder.

Kansas City, Mo.—D. S. Patterson, John Georgen and Fred P. Morrill have made the following proposition to the mayor and council of this city: "That a company to be organized by them and their associates will erect an electric light plant, and at the end of fifteen years will give the same to the city upon the following conditions: First—The city is to agree to appropriate $80,000 annually for fifteen years, pay to the company erecting the plant $68,000 annually, place the balance of $12,000 in a sinking fund each year to be invested in United States bonds, interest on the bonds to be reinvested in the same way. Second—The company will agree to furnish the city 1,000 arc lights suitably distributed over the city and keep them lighted on what

is known as the all-night schedule, each and every night. Third—At the expiration of the fifteen years the city is to turn over to the company the sinking fund and the company is to deed the plant to the city free of all incumbrances and in good condition."

London, Ont.—The power house of the London General Electric Company was burned on the night of the 29th ult., and the plant is a total wreck. The loss is about $25,000, fully insured.

New Richmond, O.—The citizens of this place are agitating the question of putting in an electric light plant and waterworks, and a special election will be held September 12 to vote on the proposition. There is some opposition to the matter, but it is believed that the proposition will carry.

New York.—Chief Engineer Daniel Ulrich has sent a report to the commissioner of parks in the Borough of the Bronx in which he recommends that the roads and parkways in that borough, and particularly the thoroughfares in the vicinity of Pelham Bay Park, be lighted by electric lamps.

Oakland, Md.—The town council proposes to buy the electric lighting plant of D. E. Offutt, if he will sell it for $13,000, and to issue bonds to provide for the purchase.

West Superior, Wis.—The council has voted to accept the proposition of William Burgess for furnishing street lighting to the city and a franchise will be prepared embodying the conditions. The following are the prices to be inserted in the contract, the term of which is five years: 150 arc lamps, 1,200 candle power, $75; 200 arc lamps, 1,200 candle power, $75; 300 arc lamps, 1,200 candle power, $72.50; all lamps over 300, $70; 150 arc lamps, 2,000 candle power, $80; 200 arc lamps, 2,000 candle power, $80; all lamps over 200 and under 300, $77.50; over 300, $75. Mr. Burgess has deposited a check for $500 as a guarantee of good faith and will file a bond for $10,000 upon the passage of the franchise for the performance of his agreement.

Wichita Falls, Tex.—J. B. Quigley of Sedalia, Mo., will probably be given a contract for the erection of waterworks and an electric light plant in this city.

MANUFACTURING, ETC.

Mexico.—The Municipal Council of the City of Mexico has granted permission to the Societe de San Ildefonso to erect overhead conductors in the public streets in connection with the plant it is putting down to supply electrical energy for power purposes.

New York.—Cuba and Porto Rico are attracting the attention of our large electrical manufacturing concerns as a promising market for their goods. An official of one of the local companies is reported in the "Commercial" as saying "that the rival concerns are busy studying the ground, with a view to sending their experts to the various cities where up-to date appliances are needed. The country is practically open to the modern ideas in use here, and there will be a great sale of American electrical goods as soon as the question of the ownership of the islands is settled. There will be electrical railroads in place of the antediluvian methods of transportation in use there now; ancient machinery in the workshops will give place to the newest of electrical equipments, and the waterways of the country will be used as motive power for plantation and city plants."

Washington, D. C.—The Treasury Department has directed Collector Bidwell to appeal from the decision of the Board of General Appraisers in assessing carbon sticks for electric lighting at 35 per cent. ad valorem. The department holds that the carbons are subject to duty at 90 cents a hundred, the rate originally fixed. —The Navy Department, through the Bureau of Yards and Docks, is inviting sealed proposals until September 24, for installing an electric light and power plant at the United States Navy Yard at Pensacola, Fla. Specifications and blank forms of proposals will be forwarded upon application to the Commandant of the Navy Yard at Pensacola, or to the Bureau of Yards and Docks, Washington, D. C.

TRANSMISSION PLANTS.

Budapest, Aus.-Hun.—A German firm lately obtained a concession from the Servian Government to exploit the water power of the Danube at the Iron Gates by establishing different industrial concerns to be worked by electricity. Work had hardly been started, however, when the Hungarian Government stopped it, declaring that Servia had no exclusive claim on the water power, and that an International Commission must decide to what degree each of the two countries might make use of it.

Denver, Col.—A correspondent of the "Times" writing from Ophir Loop, San Miguel County, Col., gives the following description of the plant of the Telluride Transmission Power Company at that place: "In the delta of the Rio and San Miguel, a short distance below the Loop, is located this great plant of which L. L. Nunn is the general manager. Two great dynamos stand up there nine feet high, two phase alternating current, 1,200 amperes each, step-up transformers to 10,000 volts on the line. The lake affords 1,200 horse power and the Howard branch 750. The transformers are six 100 KW. each, and two 375 KW. each. Water is conveyed to the plant from Trout Lake, a distance of over three miles, by flume and pipe line, with a fall of 901 feet, 436 pounds pressure to the square inch, in a fifteen-inch pipe at the plant. Its velocity is 14,520 feet per minute. The Howard fork line is about one mile in length, fall 550 feet, a pressure of 250 pounds, in a pipe fifteen inches at the plant. The current is transmitted to the great Tom Boy mine and mill in Savage basin, for power and light, a distance of about eighteen miles; the Columbia-Menona mine and mill in the same basin, Valleyview, Smuggler-Union in Marshall basin, the great 120 stamp mill on Bear creek; Gold King mine and mill, power for foundry and machine shops in Telluride, and lights for the towns of Telluride, Ophir, Trout Lake, Butterfly Mill and other points. The system is going out all over this rugged region, wherever a substantial business enterprise is planted or a town rounds into form. The dynamos weigh eighteen and one-half tons each. They are Westinghouse machines, and Mr. Nunn is adding all the valuable modern improvements to the plant as fast as they can be introduced. He is at the head of a plant similar to this one in Provo, Utah, a smaller one in Logan, that State, and his fertile brain is hatching half a dozen others, some of them stupendous in capacity."

Grand Rapids, Mich.—A company composed of New York capitalists has applied for a franchise to erect poles and wires here for an electrical transmission plant. The plan is to rebuild and improve the dam in the Muskegon river at Newaygo, where it is expected that from 1,200 to 1,500 horse power can be secured for conversion into electricity, which will be wired to this city and sold for manufacturing and lighting purposes. It is expected by the promoters that in time a number of other streams will be developed and the power sent to this city over the Newaygo-Grand Rapids wire. It is said that there are four or five streams within the same number of miles from Newaygo, from each of which a power of from 800 to 1,000 horse power could be secured.

Seattle, Wash.—The transmission line of the Snoqualmie Falls Power Company will consist of four circuits of three wires each; two circuits will supply Tacoma and two Seattle. There are two distinct pole lines. The poles are of cedar and the wires aluminum, and are run side by side from the falls for 19 miles to Renton, where they diverge, one going to Seattle and the other to Tacoma. The length of the pole line from the falls to Seattle is about 30 miles, and to Tacoma about 44 miles. The line runs through an almost unbroken forest of fir. A strip 25 feet wide has been cleared of all vegetation, and every tree within 300 feet on each side which could possibly strike the wires has been cut down, so that danger from forest fires or windfalls has been avoided. Aside from the exceptionally high voltage to be employed, the transmission line will be of great interest, from the fact that aluminum conductors will be used, and the plant will thus be the first in the world to use aluminum to transmit electricity to any distance. The wire to be used on the line contains all but 1½ per cent. of pure aluminum, the small percentage being copper. The aluminum wire while having only about 60 per cent. of the conductivity of copper was selected because of its extremely light weight, something to be taken into consideration in wire for long transmission.

MINES, ETC.

Indiana, Pa.—The "Gazette" states that it has been given out from a responsible source that the Glenwood Coal Company, at Glen Campbell, will soon commence the erection of a mammoth electric power house at Mine No. 6 which will furnish electricity for all three mines at Glen Campbell now in operation and also the new mines which will be opened on Brady Run. The electricity will be used to light the mines and haul the trains of mining cars in and out of the various mines. It is also stated that the company contemplates placing another dynamo for the purpose of furnishing light for the town.

COMPANY MATTERS.

Council Bluffs, Ia.—J. A. Patton has been appointed receiver of the Council Bluffs Gas & Electric Light Company, and will take charge of the plant pending the settlement of its affairs in the United States Circuit Court and its transfer to the bondholders.

PERSONAL AND MISCELLANEA.

Oscar Wright, superintendent of the Rockville Electric Light Company, died of typhoid fever at Rockville, Ind., on the 29th ult.

James Adams, president of the Western New York & Pennsylvania Railroad, and president of the Brush Electric Light Company, died in New York on the 2d inst.

John B. Dyar, a well-known capitalist and business man of Detroit, died last week at his summer home in Grosse Pointe. Mr. Dyar suffered some financial reverses a short time ago, alleged to have been caused by an electric road he projected from Detroit to Port Huron. Up to the time he met his reverses Mr. Dyar was a director of the Commercial National Bank, Detroit, and president of the Michigan Radiator & Manufacturing Company.

Electric train lighting has been introduced in Great Britain, more than twenty companies having agreed to adopt a uniform system, which, by the way, is radically different from that in use on American railways. Small dynamos are placed upon one of the axles of each railway car, the rotation of the axle furnishing the power for the light plant in each carriage. When the speed of the train is slower than 12 miles per hour the dynamos are automatically cut off, and in the meantime the supply of electricity for the lights is furnished by an auxiliary storage battery. The cost of installation for each car amounts to about $250, and the cost of maintenance is nominal.

The Altoona, Pa., "Gazette" states that the Pennsylvania Railroad Company has just completed in Altoona "one of the finest motive power and instruction cars ever turned out by any railroad. It is 60 feet in length, 50 feet being devoted to the office and examination room and the remaining 10 feet is utilized by a Baker heater and lavatory. The car is equipped with all the latest improvements in working airbrakes, triple brake valves, and in fact everything needed to thoroughly instruct engineers and firemen in the use of all the latest appliances. The car will soon be sent out on this division, and the men hauling the various freight and passenger trains will be taken into the car and there shown all the innovations which are likely to be made and with which they are expected to familiarize themselves."

The Toronto "Mail-Empire" says: "Mr. C. E. Green, who comes from Rochester, N. Y., but who has spent several years in Toronto, claims to have discovered a mode of producing electricity for light, heat and power purposes without either fuel or water. He declares that he can produce unlimited quantities right here in Toronto at a cost to consumers far below one-half that at present involved in the production of electrical energy. The secret of this miracle-working is, he says, a very simple affair, but he does not propose to give any clue to it just now. In a few weeks he trusts he will be able to place the scheme on a working basis."

Electrician W. W. Smith, of New Haven, Conn., is the inventor of an electrical apparatus designed for the use of physicians and dentists which is to give a new manufacturing enterprise to New Haven, arrangements having been made with the Elm City Brass Company of that city to manufacture the device. The apparatus as described in the New Haven "Register" "gives galvanic and faradic current which can be used separately or combined. It is especially valuable in cautery as the current can be raised or lowered without a break or impulse, which is something that has not been accomplished before. With the apparatus it is possible to raise or lower the voltage without a break in the circuit. There is no shock to the patient, which in itself is very important. The force may be increased gradually and when the operator is at work on delicate parts there is no nervous excitement occasioned by the higher pressure as might be by jumps and violent pressure. The apparatus is provided with a lamp which will be found useful in examining the throats of patients. The dental machine is designed for the use of dentists in their work where electricity is required. In fact the whole machine is intended to serve physicians and dentists in everything they have to do where electricity plays a part and in this electrical age these uses are many. The whole apparatus is placed in a handsome cabinet, which when closed looks like a small desk."

COMMERCIAL PARAGRAPHS.

While Iron and Steel Armored Conduit is being used to the exclusion of almost everything else in new conduit work, there is nevertheless a great deal of work where iron armored conduit cannot be used. The most satisfactory substitute under such circumstances is Canvasite Flexible Conduit. This is particularly useful in wiring or rewiring old buildings. The Electric Appliance Company, Chicago, are carrying Canvasite Flexible Conduit in all sizes from ¼ inch to 1¼ inch, and find that it has a ready sale for the above mentioned uses.

INCORPORATIONS.

The Electrical Export Company, New York—to deal in electrical goods. Capital stock, $20,000.

The Loveland Power & Electric Light Company, Loveland, O. Capital stock, $10,000.

The John Kammer Company, Chicago, Ill.—to manufacture electrical appliances. Capital stock, $50,000.

The Wisconsin Electric Storage & Water Company, Plymouth, Wis. Capital stock, $25,000.

The Northern Traction Company, Michigan City, Ind.—to build an electric railway from Michigan City to Laporte. Capital stock, $150,000.

The Gainesville Park Street Railway Company, Gainesville, Tex.—Capital stock, $100,000. Incorporators: J. M. Lindsay, George Lindsay and H. E. Eldridge.

The Wall & Cortlandt Street Ferries Railway Company, New York. Capital stock, $1,000,000. Directors: F. D. Moffat, Charles Base, K. S. Hogg, E. L. Conant, H. W. Beau, M. E. Gill and J. P. Sheffield, all of New York.

The Standard Light, Heat & Power Company, Unadilla, N. Y.—to furnish electricity for the villages of Unadilla, Gilbertsville and Otego, Otsego County; Sidney and Franklin, Delaware County, and Bainbrige and Alton, Chenango County. Capital stock, $60,000. Directors: Henry G. Canfield, Samuel E. North, J. Fred Sands and Daniel R. Buckley, all of Unadilla.

The Los Angeles Machinery Company, Los Angeles, Cal.—to buy, sell, exchange and manufacture all kinds of machinery and electrical plants. Capital stock, $10,000. Directors: R. E. Williams, Walter Jones, E. N. Williams, Theo. E. Eisen and C. Leonardt, all of Los Angeles.

The American Industrial & Commercial Union, Newark, N. J.—"to aid in organizing, managing and promoting co-operating companies for conducting legitimate and useful industrial business in any line, and to provide capi-

tal to enable them to carry on their business free from the embarrassments and perils of current indebtedness." Capital stock, $1,000,000. Incorporators: Maurice L. Muhleman, New York; Jacob F. Wycoff, Elizabeth, N. J., and Charles Vernon Culver, Reno, Pa.

The Jefferson Electric Light Company, Chicago, Ill.—to operate electric light and power plant. Capital stock, $50,000. Incorporators: M. A. Foot, Harry Ferguson, William M. Copeland.

The American Chemical & Electrical Manufacturing Company, Denver, Col.—to conduct a factory in Denver for the making of lampblack, coke, ammonia, tar, carbons and articles of a like character. Capital stock, $1,000. Directors: Mayer Harrison, Isaac Schuff and N. Burton.

The Buffalo, Tonawanda & Niagara Falls Electric Railway Company, Buffalo, N. Y. Capital stock, $1,250 000. Directors: Henry B. Smith and Hezekiah M. Gullett, Bay City, Mich.; Timothy E. Ellsworth, Lockport; James A. Roberts, George Sandrock and Clarence M. Howard, Buffalo; Benjamin L. Rand and John A. Read, North Tonawanda. Among the stockholders are John Cunneen, Michael Nellany, Dr. E. T. Smith, Gen. Benjamin Flagler, Judge E. W. Hatch, County Treasurer John C. Lammerts, Spencer J. Lawrence, Max Amberg, Frank S. Oakes, Ossian Bedell and George P. Smith.

ELECTRICAL PATENT RECORD.

Letters Patent Issued August 30, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

609,851. Electric Locomotion. Henry Van Hoevenbergh, New York City, assignor to Noah C. Rogers, same place. Filed Oct. 10, 1895. Renewed June 23, 1898.

609,977. Electric Railway-Motor. Albert Schmid, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company, same place. Filed May 10, 1894.

610,004. Rail Bond. William H. Talley, Waco, Tex., assignor, by direct and mesne assignments of nine-tenths to George H. Williams, Charles B. Eames and C. R. Sherrill, same place. Filed Nov. 26, 1897.

610,007. Contact Device for Electric Railways. Louis E. Walkins, Springfield, Mass., assignor of two-thirds to Francke W. Dickinson, same place, and George M. Jewett, Glenville, Md. Filed Jan. 24, 1898.

610,008. Contact-Rail Appliance for Electric Railways. Louis E. Walkins, Springfield, Mass., assignor to George M. Jewett, Glenville, Md., and Charles N. King, Jersey City, N. J. Filed Feb. 2, 1898.

610,009. Electric Railway. Louis E. Walkins, Springfield, Mass., assignor of one-half to George M. Jewett, Glenville, Md. Filed Feb. 2, 1898.

610,090. Electric Railroad. Benjamin C. Seaton, St. Louis, Mo., assignor to the Electric Third Rail & Signal Company, same place. Filed April 5, 1897.

610,091. Third Rail for Electric Railways. Benjamin C. Seaton, St. Louis, Mo., assignor to the Electric Third Rail & Signal Company, same place. Filed Dec. 7, 1897.

610,092. Contact Device for Electric Railways. Benjamin C. Seaton, St. Louis, Mo., assignor to the Electric Third Rail & Signal Company, same place. Filed Feb. 4, 1898.

610,093. Third Rail for Electric Railways. Benjamin C. Seaton, St. Louis, Mo., assignor to the Electric Third Rail & Signal Company, same place. Filed Feb. 4, 1898.

610,094. Electric Railway. Benjamin C. Seaton, St. Louis, Mo., assignor to the Electric Third Rail & Signal Company, same place. Filed Feb. 18, 1898.

609,818. Car-Fender. Prentis E. Law, Wilmette, Ill. Filed Oct. 14, 1897.

609,951. Car Fender. Andrew L. Smith, New York City. Filed Aug. 19, 1896.

ELECTRIC LIGHTS AND APPLIANCES.

609,924. Incandescent-Lamp Shade or Cover. Wallace H. Wells, Brasher Falls, N. Y. Filed March 28, 1898.

609,972. Hanger for Electric Lamps. William F. Murphy, Iowa City, Iowa. Filed Dec. 21, 1897.

ELECTRICAL MACHINERY AND APPARATUS.

609,990. Means for Controlling Non-Synchronous Alternating Current Motors. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company, same place. Filed March 11, 1896.

609,991. Method of and Means for Securing Constant Torque in Polyphase Motors. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed Feb. 10, 1898.

610,016. Electric Switch. Rollin A. Baldwin, South Norwalk, Conn., assignor of one-half to Heavlon Rowland, same place. Filed March 25, 1897.

610,023. Automatic Cut-Out for Magneto-Generators. William J. Bowen and Charles A. Federer, Cleveland, O., assignors to Louis Sands, same place. Filed May 26, 1898.

610,025. Alternating-Current Motor. Charles S. Bradley, Avon, N. Y. Filed Sept. 17, 1897.

610,067. Induction-Motor. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed July 22, 1897.

610,121. Controller for Electric Motors. Harry P. Davis, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed April 25, 1898.

TELEPHONE AND TELEGRAPH APPARATUS.

609,877. Tension-Regulator for Electrical Transmission of Speech. Alfred C. Cousens, Newark, N. J., assignor of one-half to George W. Gregory and John C. Edwards, Boston, Mass. Filed June 15, 1895.

MISCELLANEOUS.

609,875. Electrode for Medical Purposes. Marian N. Clarke, Wilkes Barre, Pa. Filed Jan. 8, 1898.

609,888. Clamp for Electric Wires. Sylvester S. Leonard, Chicago, Ill. Filed Jan. 24, 1898.

RE-ISSUE.

11,689. Electric-Circuit Controller. Joseph H. Bowley, Washington, D. C., assignor of one-half to John W. Stockwell, Marengo, Ill. Filed March 19, 1898. Original No. 593,510 dated Nov. 9, 1897.

TELEPHONE AND TELEGRAPH.

The Erie Telephone Company Absorbs Opposition Lines in Minnesota.

The following appears in the Boston *News Bureau* of the 2d inst.:

"The independent telephone companies in Minnesota have during the past three years constructed a system of long distance lines connecting points not reached by the Northwestern Telephone system operating in that State. Notwithstanding the fact that the Northwestern system owned and operated 7,000 miles of wire, the independents had built to nearly 300 points not reached by the Northwestern, using fully 2,200 miles of wire. Yesterday the Northwestern Company closed a contract whereby it secures by purchase 900 miles of this line and enters into an operating arrangement with the balance, all of which are to be equipped with Bell instruments and the lines and stations become a part of the extensive Northwestern system controlled by the Erie Telephone Company. The result of the purchase and agreements increases the Northwestern toll line system to nearly 10,000 miles, and as soon as the new lines can be equipped with Bell instruments, 800 stations will be to the general system. The arrangement added saves the Northwestern Company an expenditure of $200,000, representing the cost of lines into a territory already developed, and gives Minnesota the most complete long distance telephone system in the United States to date. The lines acquired that are single grounded circuits, the Northwestern will make metallic. This transaction gives to the Northwestern Company the entire toll line system in Minnesota."

The Washington *Star* says: "The War Department has received advices from Porto Rico on the work being done by the little army of Signal Service men on the island. There are 300 of these men now there and they will have to assume the control and operation of the Government lines of telegraph. The lines now, of course, are operated by the Spaniards, but when the possession of the island is transferred to the United States the Signal Service will have to take charge until the future status of the system is determined. This Government always has been opposed to a Government telegraph system and Signal Service officials say it is not improbable that the lines in the new island possession will be eventually sold to private enterprise through bids for its purchase. This, however, has not yet been taken up officially and Government control will have to be assumed at least until the ultimate disposition is determined at all the offices on the entire telegraph system of Porto Rico."

At Freeport, L. I., at the first annual meeting of the stockholders of the South Shore Telephone Company, the following directors were elected for the ensuing year: John J. Randall, George W. Bergen, William G. Miller, William D. Carter, Charles D. Smith, George P. Bergen and Henry P. Libby. The president's statement showed the business of the company to be rapidly increasing, a large number of telephones having been added to the service during the past month, and the lines having been extended to Garden City and Mineola. The statement also showed the company to be in excellent financial standing. The company's service has been introduced into the villages of Freeport, Baldwins, Rockville Center, Lynbrook, Oceanside, East Rockaway, Hempstead, Garden City, Mineola, Merrick and Barnum Island.

Extensive preparations are being made by a Franco-German syndicate to establish a telephone line from Paris to Berlin. For several months serious negotiations have been taking place between these two cities, and Brussels also, to unite the three capitals by telephone. The undertaking is silently viewed in Berlin, but arouses more or less disparaging remarks in Paris, where it is said that the scheme is entirely unnecessary. Brussels will be, of course, the medium of communication. The syndicate officers in Paris assure the public that a double wire will be used and that every precaution will be taken to provide rapid and regular service. The wires are a composition of bronze and tin, and will have a diameter of five millimeters. It is said that with this wire the resistance to the electrical current will be greatly reduced. When completed the line will be 1,000 kilometers in length, without any retransmission station, and will hence be the longest in Europe.

A special to the Little Rock *Gazette* from Camden, Ark., states that the Camden Telephone Company, established several years ago, has decided to discard their old equipments and will use the telephone switchboards and other equipments of the Southwestern Telephone Company and will act as the agents of that company at Camden for its long distance lines.

The franchise of the Osawatomie Telephone Company has been assigned to the Paola Telephone Company of Paola, Kan., and the exchanges of the two towns are now under one management.

Electrical Storms.

In the western part of Kansas wind storms occasionally sweep over the country producing electrical effects which are so pronounced that the plainsmen have named them electrical storms. T. B. Jennings of the Kansas Climate and Crop Service gives this description of them: "The wind blows with great force. It rapidly generates electricity in the person exposed to it and electrical sparks will pass from his hands to any metal he may chance to approach. The housewife has to wrap up her hands in rags as she handles her stove, or the current will play around them embarrassingly. As the sheets of a bed are touched by the hand there will be a brilliant glow of electric luminosity, and the bed clothes will fairly crackle as they are moved to and fro. These conditions are not uniform, but run in currents or streaks, and vary greatly even in the same district. The winds are mostly from the northwest. Growing grain and foliage on trees exposed to them become more or less scorched, and sometimes the grain crop is entirely destroyed. These phenomena are observed in other parts of the country, but particularly in the mountains of Colorado, where they are usually attendant on the severe blowing of the west wind. The air may be either quite dry or filled with the finest forms of vapor condensation; but nothing seems to interfere with the steady stream of electrical discharge which flows from every sharp point, whether rock, or plant, or dwelling place. A tingling and cooling sensation is felt, similar to that experienced by patients in taking the electrical bath treatment, and the multitude of discharges going on all around fill the air with a singing sound. The operators at the meteorological station at Pike's Peak experience these demonstrations in such a pronounced form that they would often be seriously alarmed were they not sensible of the comparative absence of danger. The accumulations of electric current will take the guise of flashes and balls of lightning, and the iron stove will be ablaze with continuous electrical discharges. The origin of the electricity of such storms is not yet satisfactorily explained."

The report of the Committee of the New Zealand Legislature, just issued, recommends joining the Australian Colonies with Canada and the mother country by a Pacific cable, on the basis that if Great Britain and Canada together would guarantee five-ninths of the cost of the work, New Zealand and the other Colonies would contribute the remaining four-ninths, of which amount New Zealand will contribute one-ninth. The committee also recommends that Canada be furnished with the construction, administration and maintenance of the cable, on the understanding that the contributing Colonies are to be entitled to representation and votes on matters of policy of the management and that the cable is to be owned jointly and controlled by the contributors. The report concludes with advising that a conference of the Colonies concerned be held in New Zealand.

Alex. I. McLeod of the Detroit Telephone Company says there is no connection between his company and the new company that has been formed in Cleveland, with a capital stock of $1,000,000, to build cheap telephone and telegraph lines in Cleveland and all over the State of Ohio. To a Detroit *Tribune* reporter Mr. McLeod said: "H. A. Everett, the leader in that enterprise, is a stockholder in our company and at one time was a director. The Cleveland company is going to be a strong organization and our construction company expects to sell them a large part of their equipment. The 'phone they will use is practically the same as ours."

At a meeting of the directors of the Pacific Cable Company, held at the office of J. P. Morgan & Co., New York, on the 1st inst., plans were considered for establishing cable communication with the Philippines, the Asiatic coast, Japan and Australasia via Hawaii. Surveys for a duplicate cable via Sitka and the Aleutian Islands were ordered. James A. Scrymser, president of the Pacific Cable Company, sails from Vancouver for Japan on September 12.

The statement of the output of instruments by the American Bell Telephone Company for the month ended August 20 shows: Gross output, 24,863, increase over same month in 1897, 9,096; returned, 12,022, increase 1,868; net output, 12,841, increase 7,228. From December 21 to August 20: Gross output, 212,747, increase 69,202; returned, 95,328, increase 33 327; net output, 117,419, increase 35,875. Total output August 20, 1898: 1,036,541; August 20, 1897, 851,171; increase, 182,370.

New Companies Incorporated.

The Gordon Telephone Company, Chester, Ill. Capital stock, $5,000. Incorporators: A. G. Gordon, E. R. Gordon and Clarice Gordon.

The Dakota Central Telephone Company, Aberdeen, S. D. Capital stock, $100,000. Incorporators: W. G. Bickeyhaupt, M. H. Zeitlow and L. W. Crofoot.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12@12⅛c.; Lake, 12.15@12.25c.; casting, 11⅞@12c.

The Chicago Telephone Company has declared a dividend of 1 per cent., payable on and after September 6.

Stockholders of the Union Traction Company of Philadelphia will convene in annual meeting in that city on September 21.

The Philadelphia Traction Company has declared a semi-annual dividend of $2, payable October 1. Books close September 20 and reopen October 1.

The Brooklyn (N. Y.) Rapid Transit Railroad Company reports gross earnings for August of $563,257, an increase of $85,857 as compared with the same month last year.

The Chicago City Railway Company has declared a dividend of 3 per cent. on its capital stock, payable September 30. Books close September 16 and reopen September 21.

The North Shore Traction Company, Boston, has declared a semi-annual dividend of 3 per cent. on its preferred stock, payable by the Continental Trust Company of New York, transfer agent, on October 1. Transfer books close September 13 and reopen October 19.

It is shrewdly suggested by the Boston "Advertiser" that the market is controlled more by men than by figures. The knowledge that Morgan or Keene or Flower or Rockefeller is interested actively in any property is received with much more pleasure by the Street than any cold-blooded statement of earnings or expenses.

The United Electric Securities Company, Boston, has purchased of its collateral 5 per cent. bonds an amount sufficient to absorb $72,632 as follows: Fifth series, $10,000 at 100; seventh series, $3,000 at 99⅜; ninth series, $46,000 at 101.57; tenth series, $13,000 at 99.40. The annual meeting of the company will be held at Portland, Me., September 8. Books closed August 25 will reopen September 9.

The Buffalo (N. Y.) Railway Company reports for the year ended June 30: Gross earnings, $1,356,494, increase over 1897, $29,406; operating expenses, $678,135, increase $9,283; net earnings, $678,359, increase $20,123; other income, $28,779, increase $4,985; total income, $707,138, increase $25,108; fixed charges, $420,348, decrease $6,774; balance, $286,790, increase $31,883.

A mortgage of the Gloucester Electric Company, Gloucester, Mass., to the amount of $50,000 to the Old Colony Trust Company of Boston has been recorded in Salem. This mortgage is to raise money to pay bonds of the amount named. A mortgage of the Plum Island Street Railway Company of Newburyport to the amount of $33,000, to the International Trust Company, was also recorded in Salem. This is to secure money to pay bonds.

The Edison Electric Light Company of Brooklyn issued a circular to stockholders on the 31st ult. describing the manner of conversion to the Kings County Electric Light & Power Company. Edison stock is to be deposited with the Central Trust Company with power to them to transfer. After the receipt of two-thirds of the stock the Central Trust Company will assign it to the Kings County Company and receive the purchase money, which is to be held in trust as an absolute protection for the Edison Company's new securities.

The Farmers' Loan & Trust Company of New York has commenced suit in the United States Circuit Court, Omaha, Neb., against the Council Bluffs Gas & Electric Light Company, to foreclose the first mortgage of $250,000, payment of principal and interest of which it is alleged has been defaulted. The appointment of a receiver is asked for. Hon. George F. Wright, originally the principal stockholder of the Gas & Electric Light Company, is quoted as saying that the suit was for the purpose of allowing the Eastern stockholders who are reorganizing the company an opportunity to buy in the plant. When this is done the reorganized company will issue new bonds at a lower rate of interest.

The manipulators worked General Electric stock last week "for all it was worth," putting it up about 6 points by circulating rumors of equipment contracts, increased orders from abroad, etc. There was a rumor also that a settlement had been made with the preferred stockholders. The Boston "News Bureau" of the 1st inst., however, states that so far as the Boston interests in the matter are concerned no overtures to the preferred stockholders' committee have been made. The same paper had the following: "Private wire dispatches state that a bull pool has been formed in General Electric. There is talk of early electrical equipment of Manhattan, with good prospects of General Electric securing the contract. [The old game.] Price, McCormick & Co. were large buyers of the stock."

The report of the Street Railway & Illuminating Properties for the year ending July 31 furnishes the following: Securities from previous year, par, $5,157,955; decrease, $471,045. Securities received from other companies against adv., etc., $904,193; increase, $877,572. Total, $6,062,148; increase, $406,527. Par value securities sold, paid or disposed of, $1,838,158; increase, $1,340,492. Securities held by trust at par, $4,223,989; decrease, $933,966. Total, $6,062,148; increase, $406,527. The Street Railway & Illuminating Properties was formed on the basis of the General Electric Company's treasury assets to relieve it in a measure several years ago. We get this information from the N. Y "Journal of Commerce."

The Nassau Electric Railroad Company, Brooklyn, reports for the year ended June 30: Gross earnings, $2,054,080, increase over 1897 $293,518; operating expenses, $1,259,838, increase $214,474; net earnings, $794,242, increase $79,044; other income, $63,610, decrease $1,102; total income, $827,857, increase $77,942; fixed charges, $810,028, increase $100,718; surplus, $47,824, decrease $22,776; betterments, $388,428, decrease $697,661. The general balance sheet as of June 30 shows: Assets—Cost of road and equipment, $9,301,229; rights to use tracks of Kings County Electric Railway Company, et al., etc., $2,000,000; supplies on hand and materials, $26,759; additions and betterments, leased lines, $1,782,673; prepaid insurance, $25,558; open accounts, $44,077; cash on hand, $87,971; bills receivable, $22,000; total, $13,290,268 Liabilities—Capital stock, common, $6,000,000; preferred, $4,849,000; loans and bills payable, $1,804,655; interest due and accrued, $60,612; accounts payable, $131,629; accrued taxes, $84,754; rentals due and accrued, $184,913; profit and loss (surplus), $174,673; total, $13,290,268.

In regard to the change of motive power on the Third Avenue lines in New York, Edward Lauterbach, the counsel of the company, is quoted as saying: "The underground trolley which is to replace the cable and other traction methods of the company will be in operation in sixty days after the beginning of the work on the main Third Avenue line. Before the snow flies the cars of the Forty-second street line will be operated by electricity and those of the 125th street line in ninety days. The Dry Dock line will be left over until the spring. The change from cable to trolley will result in little, if any, interference with the operation of the Third Avenue system, except perhaps on the Forty-second street line. All the changes and improvements contemplated for the system will cost from twelve to fifteen million dollars. The new cars will be lighted by electricity, will be handsomely equipped and properly heated for the cold season. We are reaching out with the Union Railway Company and improving its service steadily, and our relations with the Metropolitan Street Railway Company continue to be pleasant. The change on Third avenue from cable to electricity was brought about by the force of sound logic and no considerations that involved delay were heeded."

ELECTRICITY.

Vol. XV. NEW YORK, SEPTEMBER 14, 1898. No. 10.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4081 Cortlandt.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	2.00
FOREIGN COUNTRIES,	4.50
SINGLE COPIES,	10 cents

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

The Electric Furnace. The electric furnace, as Prof. Trowbridge once aptly expressed it, has revolutionized certain processes in the arts. This is probably due to the fact that the electric furnace differs from other furnaces in that it localizes the heat in a narrow compass and thus an enormously high temperature can be obtained. As is well known, the ordinary electric furnace consists of a box-like arrangement of limestone in which a cavity is cut, the electric current being led into the latter by means of two hard carbon electrodes situated one on either side. On the formation of an arc between the terminals of the electrodes the temperature obtained is usually between 6,000 and 7,000 degrees Fahrenheit, at which heat oxides of even the most refractory metals are immediately fused. Aluminum is thus produced from its oxide very economically, as well as carbide of lime or calcium carbide from which acetylene gas is made.

Various attempts have been made to apply the electric furnace to the smelting of iron ore on a large scale, with questionable success. One type of electric furnace designed for this purpose consists of a large tank filled with alkaline water, in which crucibles with perforated bottoms containing the ore to be treated are suspended. An electrical conductor is connected with the solution below the crucibles, at one side of the tank, while movable metal electrodes come in contact with the ore in the crucibles. In this type of furnace the circuit is completed when the surface of the alkaline solution is raised through the medium of a plunger, and comes in contact with the crucibles. The resistance of the solution in this case is supposed to develop the requisite amount of heat to smelt the ore.

Whether an electric smelter such as the above, or any other form for that matter, can be successfully used in a commercial way to smelt large quantities of ores remains to be seen, but so far the electric smelter has not superseded the old-time furnace. The electric arc is, however, unquestionably finding a sphere of usefulness in the heating of metals for forging. This method would seem to be applicable not only to blacksmith work but to carriage factories, boiler shops—in short in all places where iron forging is a part of the work. Of the various types of electric forges now on the market what is known as the liquid forge is probably the most striking, as its operation appears to be based on a principle directly contrary to the law of nature, in that a piece of metal becomes red hot while immersed in water. The forge itself consists of a tank provided with a metal lining to which the positive wire of a dynamo is attached. The negative conductor is soldered to a pair of tongs with insulated handles with which the piece of metal to be heated is handled. The principle on which the operation of this forge is based is both simple and ingenious. The electric current in passing from one terminal to the other decomposes the water, and a film of hydrogen is formed around the negative wire and the piece of metal to be heated. Hydrogen being a bad conductor of electricity creates a resistance to the passage of the current and causes the energy of the current to be transformed into heat, which immediately raises the temperature of the bar to be heated. A forge of this description was on exhibition at the Chicago World's Fair and created considerable comment. The advantages claimed for the electric forge, and which would seem to be well founded, are economy of space, saving of fuel, time and labor, as well as cleanliness.

The American Street Railway Association Convention. The Seventeenth Annual Convention of the American Street Railway Association, the proceedings of which will be found elsewhere in this issue, was probably the most successful yet enjoyed by this body. The papers read during the four days of the meeting were comparatively few in number, but the lack of quantity was more than made up for in quality. The attendance was everything that could be desired, there being over 260 delegates present, representing 161 street railway companies, over 130 non-members and almost 200 ladies. The headquarters of the Association was the Hotel Brunswick, but the exercises took place in the Mechanics' Building. Probably one of the most interesting papers read was that entitled "Comparative Earnings and Economy of Operation Between Single and Double Truck Cars for City Use," by Mr. Richard McCulloch, which may be found in full on another page. The writer did not attempt to prove that either the single or the double truck car is the better type. He merely discussed the subject with a view to bringing out the strong and weak points of each type in such a way that the results might be applied to special or local conditions. In the discussion which followed, the general opinion seemed to be in favor of the double-truck car. The other papers read attracted considerable attention, especially that entitled "Cost of Electric Power for Street Railways at Switchboard, both Steam and Water," by Mr. R. W. Conant.

The social features of the Convention were most agreeable, there being a number of pleasant trolley rides to neighboring points of interest, a clambake, a drive in the park, and a shopping trip for the ladies.

The return of the Street Railway Association to

the place of its birth after seventeen years of wandering should long be remembered by all those who were fortunate enough to be present.

Untimely Death of Dr. John Hopkinson.

In our issue of August 31 we referred in a short paragraph to an announcement of the sudden death of Dr. John Hopkinson, the celebrated English electrical engineer, and that of his son and two daughters while ascending the Dent de Veisivi in Switzerland. This rumor, for it was scarcely more than such at the time, has, we regret, since been confirmed. The untimely death of such a capable electrical engineer and physicist will be deeply deplored by the electrical fraternity on both sides of the Atlantic.

Dr. Hopkinson was born in Manchester, Eng., in 1849. After studying at various schools he entered Cambridge University and while there took the degree of D. Sc. at the London University. He was at one time in the early part of his career assistant to Sir William Siemens, and was connected with some of the first electric traction experiments in Great Britain. The electrical equipment of the celebrated City & South London Railway was designed by him and carried out under his supervision. He was twice elected President of the London Institution of Electrical Engineers and was closely associated with numerous other engineering societies. He was a member of the Council of the British Association and was a fellow of the Royal Society.

Dr. Hopkinson was a frequent contributor to the proceedings of various engineering societies, his best known papers probably being those which relate to magnetism and to the theory of dynamos, although his contributions treating of the electrostatic capacity of bodies are of importance. Dr. Hopkinson possessed the two qualities rarely met with among engineers, namely, a high degree of theoretical knowledge and wonderful practical ability. He introduced many improvements in light-house machinery and brought out what is known as the group flashing apparatus. In short, there is scarcely a branch of electrical engineering which does not bear the mark of his high professional ability by some more or less important improvement. In the death of Dr. John Hopkinson the electrical profession has unquestionably lost one of its most brilliant and hardest workers, which cannot be too deeply deplored.

Electrical Apparatus of the New Experimental Tank in Washington.

While the small tank which is now being constructed at Washington Navy Yard for testing the speed of miniature war vessels is an experiment in every sense of the word in this country, it is not so on the other side of the Atlantic, where they have been in use, notably in England, since 1872. However, there is probably no tank of this nature in existence at the present time abroad so complete in every detail as will be the one now in course of construction at Washington. The many and persistent efforts of Chief Constructor Hichborn, of the Navy, for the introduction of this facility for changing the rate of speed of proposed vessels from an unknown quantity to an assured certainty, were not productive of effect until Congress two years ago made an appropriation of $105,000 to be devoted to this purpose. The tank it is now confidently expected will be completed by October 1. The purpose to be gained is that all uncertainty in the speed of proposed vessels for the Navy which at present cannot be demonstrated until the trial trip is made, and after an expenditure of several millions of dollars and years of time, can be determined by means of models which it is proposed to test under conditions similar to what the vessels they represent would have to undergo. Thus when the desired speed is not attained the model can be altered so as to meet the requirements, or if this does not prove satisfactory, the model itself may be cast aside and new plans designed.

The building to be devoted to this purpose has been erected in the Navy Yard at Washington, along the east river front. Its dimensions are 500 feet long by 50 feet wide, and has two small extensions at either end. The interior construction shows a basin of concrete 370 feet long by 43 feet wide, with a depth of 14 feet in the center. In one of the extensions will be the heating, ventilating and filtering apparatus, and in the other the necessary electrical equipment. The electrical installation will supply the necessary power for driving the model-towing carriage. The speed will vary from the slowest up to an actual speed of not less than 2,000 feet per minute. The approximate weight of this towing carriage is 45,000 pounds, and it is designed to be driven by four electric motors arranged in pairs. These motors will be wound so as to have a maximum potential of 250 volts, and at the voltage named all four motors acting through suitable gearing will develop the necessary power for attaining the highest rate of speed, i. e., 2,000 feet per minute. The armatures will have a speed of about 800 revolutions per minute, and will be fully capable of carrying the required load for five minutes or even longer if necessary. The controlling gear will be located on the towing carriage. This controlling gear will be so apportioned that not less than 45 different speeds will be available as follows: From 0 to 600 feet per minute, so arranged as to include 24 speeds, increasing by increments of 25 feet; from 600 to 1,300 feet per minute to include 14 increments at a distance of 50 feet apart; from 1,300 to 2,000 feet to include 7 increments of 100 feet distance.

The field of each motor is provided with a rheostat and a Weston ammeter. A voltmeter is connected with the armature circuit of each motor, and again there is one on the main circuit.

The towing carriage will be braked by electricity, the braking arrangement being able to bring the carriage to rest from a speed of 1,000 feet per minute, and that in a distance not exceeding 100 yards. The generator will be of the multipolar direct-connected type. That this tank will prove of great value cannot be doubted, and many times its cost will unquestionably be saved to the Government by a judicious use of the electric towing carriage.

Under the Searchlight.

Notes and Comments on Various Topics.

THE General Electric Company had an "exhibit" at the Boston Street Railway Convention in the form of a globe 24 feet in diameter representing a mapped figure of the world. At night small glow lamps indicated spots on this globe which extensive advertising had enabled the company to reach with its goods, and we are told that the demonstrator pointed with special pride to an isolated kraal in South Africa where there was some of the G. E. apparatus in operation. If any shareholder of the company happened to see this hollow monstrosity, he must have thought: "Well, that is a big thing—on the surface—but there's nothing in it,—and in this respect it fitly represents the company, which has just cut off 40 per cent. of its capital stock, and has paid no dividends for five years. What does it profit if we gain the whole world and lose 40 per cent. of what it cost us to get it?"

* * *

THE engineer in charge of a large electric plant in New Orleans is an exceedingly intelligent young man and usually takes delight in exhibiting the machinery to visitors. He had an experience the other day, however, that greatly cooled his ardor in that direction, as we learn from the *Times-Democrat*. A couple of ladies from abroad had dropped in to see the apparatus, and, as usual, the engineer acted as cicerone. Among other things of interest in the place is a huge belt passing some eight feet above the floor, which generates so much of what is called "static electricity" that the effect on one who stands beneath is literally hair-raising. This is a favorite experiment about the dynamo room and the surprise of strangers always raises a good-natured laugh. With the fact in mind, the young engineer requested one of the ladies to step to a spot which he indicated under the swiftly-moving belt. She innocently did so, but at the next instant clapped both hands to her forehead and uttered a loud shriek. The luxurious curls that had adorned her brow had disappeared in space, and, as a matter of fact, were adhering tightly to the surface of the belt and making exactly 120 revolutions a minute. "Really I—I had no idea—that is, I—" stammered the horrified electrician. "You are a brute, sir!" interrupted the lady, "a low brute," and since then experiments in static phenomena have been discontinued at the establishment.

P. A. B. WIDENER, one of the incorporators of the American Indies Company, says: "We are authorized by our charter to undertake nearly anything down there. We have with us the wide-awake men in Cuba and Porto Rico, who know the soil and what is in it, and we are going into anything that will make money. It may be steamships, it may be oil, it may be gas, it may be sugar, it may be iron, it may be trolley lines and telephones. We will tell the public further when we are ready. We are going to put up all the money ourselves at present; later we will probably have something to offer the public."

* * *

CONSUL GENERAL DU BOIS reports to the State Department from St. Gall, Switzerland, that on January 1, 1898, 204 lines of electric street railways, with a mileage of 2,250.4 kilometers, were in operation in Europe. The rolling stock consisted of 4,514 motor cars. Germany has 65, France 44, Austria-Hungary 13, Great Britain 24, Switzerland 23 and Italy 11 electric street railways. The system most in use is the overhead trolley, which is operated by 172 lines, while 8 lines have adopted the underground trolley, 8 lines the third-rail system, 13 lines storage or accumulator cars, and 3 lines have a mixed system of overhead trolley and accumulators at certain points of their lines.

* * *

IT is a curious instance of our natural conservatism, says *Lightning*, London, that though science has long solved the problem of artificial cold, no one dreams of cooling his house in summer except by opening the windows, or at most by the use of a ventilating fan. Artificial heat, of course, has been sanctioned by long usage, though the means generally adopted are almost as extravagant as it would be to cool a room with flasks of liquid air. Except for the expense, this would be a pleasant way of relieving the heat and closeness at a public dinner. A few of Professor Dewar's flasks placed at intervals on the tables would make effective table ornaments, would cool the room and renew the atmosphere. Moreover, if liquid oxygen were to take the place of liquid air, who knows what exhilarating effect it might have on the oratory, which is often in need of some such stimulant, while should a guest chance to upset one of the flasks, the excitement might rise to fever pitch.

Annual Meeting of the Street Railway Association of New York.

At Manhattan Beach Hotel on Tuesday, the 13th inst., the members of the above Association met to hold their Sixteenth Annual Convention. The day was pleasant and the delegates, "swept by ocean breezes," felt all the exhilarating influences of the locality and were in a most happy mood. The attendance was quite large, which would seem to assure a full and interesting discussion of the papers to be read, but owing to our forms being put to press we are obliged to defer an account of the proceedings until our next issue. The Convention will continue for two days, the annual banquet being held last night.

AMERICAN STREET RAILWAY ASSOCIATION.

A Great Gathering of Representative Men at the Boston Convention.

WELCOMED BY THE MAYOR AND CORDIALLY RECEIVED BY THE PEOPLE.

Full Report of the Proceedings—Official List of Delegates in Attendance.

The Seventeenth Annual Meeting of the American Street Railway Association was held from the 6th to the 9th inst. at the Massachusetts Charitable Mechanic's Association Hall, Boston. On opening the Convention on the 6th, President Albion E. Lang, of Toledo, O., called the members to order at 11 o'clock A.M., and introduced Mayor Quincy, who delivered an address in which he said:

Mr. President and Gentlemen of the American Street Railway Association: It gives me a great deal of pleasure to welcome you to the city, and to express the hope that the deliberations of this large meeting of the American Street Railway Association may be both pleasant and profitable. The size of this gathering, the wide extent of the representation in this Convention, the financial magnitude of the interests involved, afford a striking illustration of the rapid development which is taking place in the electric transportation interests of the United States. They have to-day won a position as one of the greatest—as one of the most important interests of the country.

I think the economic and social results which are to follow from the development of the electrical street railway are only second in importance to those which have followed from the development of the steam railroad. I think the street railway has progressed far enough in its evolution—although it has by no means filled its full field in this country, or reached the limit of its usefulness—it has progressed far enough to enable us to see that it is an important agency in the promotion of civilization.

Electric railways tend to bind together the various cities and the various towns and the various communities into which mankind is divided into a great unit of communities, all of which understand each other better through the cheap facilities for moving about which have been brought to the world by this comparatively new agency of electricity. And so I am very glad to welcome this Convention to-day as representing a new and potent force which has come into the world by the advancement of mankind.

I am confident that this Street Railway Convention, the largest and most important, I believe, which has been held up to the present time, with its mechanical and electrical exhibits, and with the important matters which are to come before it for consideration, will accomplish something for the still farther progress of this great interest and this great industry. The people of Boston are always glad to welcome these national conventions. Boston has a great electric street railway system. Not only has she one of the very greatest, and I believe one of the very best, street railroad transportation systems to be found anywhere in the world, but we have in the suburbs of Boston, in that chain of cities and towns which encircle Boston proper, which constitute Greater Boston, embracing as it does a million people or more within its limits, we have in these outlying cities, and towns as well, highly developed systems of suburban and of interurban street railway transportation. I am sure, therefore, that this Association could not have selected a better center in which to hold its gathering this year, in which to take account of the progress that has been made in electric street railway work during the last year, and in looking forward to the progress that is still to be made, than in this city of Boston. I can only wish that your visit may be pleasant as well as profitable, and will say in conclusion that if there is anything which the city of Boston, as a corporation, or the citizens of Boston individually, can do to make your stay here a pleasant one, I am sure that it will be very cheerfully done. (Applause.)

President Lang—Mr. Mayor, I am sure that I express the sentiments of this organization when I say that we are glad to be with you. On behalf of the members of this Association I tender to you our thanks for the very cordial welcome you have extended to us and for the interesting remarks you have made.

On motion of Mr. McCormack of Brooklyn, a rising vote of thanks was given the Mayor for his kind address of welcome to the Association.

President Lang—The next order of business will be the calling of the roll. I will say that the Executive Committee have decided to make a departure in the method of calling the roll—we will consider the roll called by accepting the registration at the door as the evidence of the companies represented and the gentlemen who represent them. In that way we will facilitate our business. The next order of business is the reading of the minutes of the last meeting, and unless objection is made the minutes will stand approved as printed. We will now give an opportunity to companies represented that are not members of the Association to acquire membership.

The following companies then joined the Association: Elmira & Horseheads Railroad Company, Elmira, N. Y.; Portchester Traction Company, Portchester, N. Y.; Portland & Yarmouth Electric Railway Company, Portland, Me.; Portsmouth Street Railway Company, Portsmouth, Va.

Mr. Kerper (Dayton)—Mr. President, I desire to offer the following resolutions:

Whereas, The Executive Committee of this Association, at its meeting held in Boston, January 25 and 26, 1898, owing to its inability to secure a proper hall for the annual meeting of the Association at any other time, issued its call for the meeting of the Association to be held in Boston, September 6–9, 1898:

Resolved, That the action of said Executive Committee be and the same is hereby approved, ratified and confirmed, and this meeting is hereby declared to be the regular annual meeting of the Association for the year 1898;

Resolved, That all of the business of the Association be proceeded with at this meeting in accordance with the by-laws of the Association applicable to regular meetings called and held within dates provided by paragraph 7 of said by-laws.

The resolutions were seconded by Mr. Hamilton of Chicago and unanimously adopted.

The next order of business was the address of the President, which is here given in full:

PRESIDENT LANG'S ADDRESS.

The American Street-Railway Association—Gentlemen: We are to-day, for the seventeenth consecutive year, assembled in furtherance of the objects of our Association, under conditions most favorable to a pleasant and profitable meeting; for we are in the house of our father, the city of our birth.

As the presiding officer of the Association, and in the name of the street railway men of Boston, I bid you a hearty, sincere and joyous welcome.

Amid the circumstances of this meeting, our thoughts naturally turn to the time, the persons and the conditions existing when the Association was formed. Some then present are with us to-day, and whether residents of Boston or not, certainly experience a pardonable pride in the growth and achievements of the Association as shown by its published proceedings and emphasized by the large number in attendance.

Of the Boston people who were present at the outset, Calvin A. Richards, president of the Metropolitan Railroad Company, now a part of the Boston Elevated system, was a conspicuous and active member. In 1884 he was elected president of the Association, and those who knew him best feel a deep grief that death has robbed us of a member whose welcome, if present, would know no bounds.

As I trace the history of the Association from its inception, I am convinced that its founders, in the words of Emerson, "builded better than they knew," for is it not remarkable that they should have chosen a name and set forth in our constitution the objects of the Association so wisely and well that no material change has been required to adapt them to present conditions, which are so radically different from those then prevailing?

The constitution then as now says: "The object of this Association shall be the acquisition of experimental, statistical and scientific knowledge relating to the construction, equipment and operation of street railways," etc.

The need for experimental knowledge in connection with a mule goes without saying, and statistical and scientific knowledge with reference to harness, cars or strap-rails sounds very ancient as compared with engines, boilers, generators, girder rails, vestibuled cars, lightning arresters, ohms, volts, watts, amperes, etc., the familiar subjects of to-day. I do not mean, however, to belittle the value of the investigation, discussion and association of the earlier days, because there are too many veterans present (and I might myself be called one) who can testify to the great benefit derived therefrom. It does seem, however, that the necessity for holding meetings in different cities was greater formerly than now, for in order to know very much about what others had done or were doing we had to go to them, whereas now we can see almost everything in connection with our business in the room below, except the mercurial portion known as the State Legislature, common council, tax gatherer and ubiquitous damage lawyer, so-called.

That this is a fair inference is also shown by the records, for the second meeting was held in Chicago, which then as now claimed to be the metropolis of the West, but disputed by St. Louis. While it was doubtless an enjoyable meeting, Chicago was apparently too much of a shock to the nervous systems of our Eastern members, so it was determined to return East the following year and New York was selected. Of course, New York never fails to interest, but there is one obstacle always difficult to overcome in meetings at that point, which is that one cannot remain long enough to see it all. What the delegates failed to find there, however, they looked for the year following at St. Louis, and it proved so good that they naturally looked for more nearby, hence next sought out Cincinnati. Cincinnati, as was expected, proved to be ideal, but the East offered so many attractions in the contest for location that Philadelphia captured the Convention following.

Dignified and made bold by the Philadelphia meeting the cry became, "On to Washington." The pleasure and profit of that meeting cannot be doubted, but the West was evidently becoming jealous, and to secure another meeting played its trump card and Minneapolis won out. It goes without saying that this meeting was profitable to the Association as well as to the good people of Minneapolis. Electricity as a motive power was at that time so far advanced that all knew it was bound to come. Its discussion consumed nearly all the time of the meeting, and we left the Minneapolis people more strongly impressed than ever before that they had made no mistake in adopting electricity as a motive power and that they wanted still more of it.

In journeying to Buffalo the following year the Association was well repaid, for much progress along electrical lines was found, and it undoubtedly stimulated the movement further in this direction, hence a dash was made for Pittsburg the following year. No one will ever forget that great concern, the Westinghouse Electric & Manufacturing Company, which was then and is still so energetic and progressive in the electrical field, and which proved to be such an interesting feature of the meeting.

In going to Cleveland for our next meeting we did wisely, for we there found roads and power houses further advanced towards the goal of perfection than could perhaps at that time have been found at any other place in the country. At the Milwaukee meeting the year following we were met with the most extensive display of electrical apparatus witnessed up to that time, presided over by scores of ever-watchful, energetic and intelligent supplymen, and our meeting proved to be unusually profitable. By this time we were all so firmly established on the electrical foundation that to see an elec-

trical road or inspect electrical appliances was no novelty, but, still searching for greater things, we turned towards Atlanta. We not only found a great exposition of the products of the country here assembled, but very much in the electrical line to interest us. The cordiality of our reception by the people was a crowning feature of this meeting.

In turning our steps toward Montreal, a year later, we endeavored to give of the good things we had seen and experienced at former meetings, and to acquire further knowledge from our Canadian brothers. It was the first attempt at holding a meeting beyond our borders, and for various reasons was slimly attended; still it was not void of profit, for it revitalized the Association to such an extent that the meeting at St. Louis the following year was unusually interesting and valuable. Having had a foretaste of the place, we, of course, were eager to return, and our reception by the people could not have been more cordial. It was left for Niagara Falls, however, to overshadow what up to that time had been considered great, and to reveal to us the vast in electrical units and in nature. We also found the manufacturers and supplymen present in abundance, and our meeting there was voted a success in every particular.

I have thus briefly recounted our movements and spoken of the motives which it has seemed from the best information at hand prompted the Association in selecting its places of meeting, and the value of such selections and other reasons why the Association has grown to its present proportions and standing. Its growth and experiences, like all such organizations, have not been without some severe trials, but unlike the prodigal son, we have wasted none of our substance in riotous living, but have improved at each successive step, and now reach home—not only the birth-place of the Association, but the home of the electrical industries in a larger sense perhaps than any other locality in the world. The people of Boston not only furnished money with a lavish hand to carry forward the work of developing the subtle power now so useful to us and all mankind, but also much of the brains and energy needed to make its use practical. Of this fact, one circumstance will bear witness, and it is that Mr. C. A. Coffin, a Boston man, is still retained at the head of the largest electrical manufacturing corporation in the United States if not in the world.

Having laid in this city the foundation of the splendid structure we have since reared, it is very proper that we should return and dwell therein for a few days. Everything gives promise of this being the largest meeting in our existence. If we do not make it one of the most valuable, the fault will be with ourselves. Let us hope to leave such an impression that the Boston people will say—"It was good to have them with us."

In the growth and development of our Association and the business we represent, let us not forget the priceless and unrivaled assistance rendered by the technical press. Without a spokesman, a guardian ever-faithful to our interests as they have been, our progress would have been slower and our pathway exceeding rough. All honor to those devoted publishers and editors!

Nor must we for a moment forget (if we could) the indefatigable supplyman, for he is the noblest Roman of them all. It is his courage, foresight and energy in taking up the new and useful article, and pressing it upon our attention, that helps to effect economies. We may sometimes be prematurely persuaded, but that is not the fault of the supplyman; it is simply one of the arts of his trade necessary for us to learn. But, seriously, without them the meetings of our Association would be materially weakened and lose much of their interest and value. Let us then not fail to give them and their exhibits all the attention and examination time will permit.

The Executive Committee has prepared a very excellent list of papers to be read, and I trust that all will join in giving them generous discussion. Some of the writers of the papers have told me that they expected more benefit would be derived by members from discussion than from the paper itself. This should be inducement enough to keep all in constant attendance. Bear in mind that in so doing we are also promoting the best interests of the Association, as well as honoring the writers of the papers, which is their due and our duty. While on this subject let me here call attention to the necessity of having at our meetings papers which will interest all the members—not only the mechanical and electrical engineers, but the general managers and even presidents of companies. We need all these officials with us at every Convention, hence we must provide something of interest to them.

Each and every member must be made to feel that he has been benefited by attending our Conventions, and likewise the company represented, or our Association will cease growing. As a result of our deliberations, economies should follow without injury to the public service, all of which will tend toward a further realization of the objects of our Association, which are "the establishment and maintenance of a spirit of fraternity among the members" and in the largest degree "the encouragement of cordial and friendly relations between the roads and the public."

Under the head of general business as provided in our by-laws, or at some other appropriate time, a sort of experience meeting or informal discussion of all subjects relating to our business should take place, where each member shall feel free to ask any question that occurs to him upon which he desires information, and some one stand ready to answer.

I venture to suggest a few subjects arising almost daily where in this way very helpful information could be obtained, viz.:

1. The suburban railroads—on what terms and conditions should they enter over our tracks, and how can their building be encouraged.
2. The issuing of transfer checks or tickets, and how abuses connected therewith can be limited.
3. The equipping of buildings with automatic sprinklers and the economies resulting therefrom.
4. The cost of electric welding of rail joints and the saving effected in current and cars.
5. The discussion or agitation of municipal ownership of franchises and the most intelligent way to treat the subject.
6. To what extent companies should engage in the amusement business and the best methods of conducting the same.
7. A comparison of the cost of materials and supplies and expenses of operation.
8. How best to promote the interests of employes, and in return secure from them the highest degree of service and loyalty.

These and many other subjects of kindred nature considered in this manner would awaken great interest.

I desire to call attention to our fellow-workers and associates, the Accountants' Association, which hold their meetings simultaneously with ours each year, and are even now in session in another part of the building. The whole business of the street railway revolves around the accountant's office, and many of us can attest the value of having efficient persons in charge thereof. It is with the hope of enabling them to make their services more valuable to their respective companies that the Association was formed, hence they should receive every assistance it is possible for us to render. I bespeak for them your cordial co-operation.

In closing I wish to thank our efficient Secretary and the Executive Committee for their cordial aid and support during the year, and to assure the members of the Association of my great appreciation of the honor of being called a year ago to the office of President.

The President—The next business in order will be the report of the Executive Committee, which will be read by the Secretary.

The minutes of the meetings of the Executive Committee held at Boston January 25 and 26 and September 5 and 6, 1898, were then read. These minutes contained an account of the routine business of the committee, among other things fixing the date of the Convention, arranging for the exhibits, assigning the topics for papers, regulating the issuance of banquet tickets, etc.

The committee also recommended the adoption of the following rules for the Convention:

1. No member will be recognized by the President unless he shall announce distinctly his name and address.

2. Speeches will be limited to ten minutes unless the time shall be extended by the Convention.

3. Members who desire to offer resolutions or other matters to be considered by the Convention are requested to submit them in writing over their signatures to the Secretary.

Mr. Hamilton (Chicago)—I move that the report of the Executive Committee be received and approved, and the recommendations presented be concurred in, and that the thanks of the Association be extended to the officers and Executive Committee for the very able manner in which they have conducted the business of the Association for the past year.

The President—We will now listen to the report of the Secretary and Treasurer.

The report of the Treasurer was presented, showing the financial condition of the Association to be as follows:

Balance, October 18, 1897	$2,931.48
Receipts	6,376.65
	$9,307.65
Expenses	5.651.37
Balance, September 5, 1898	$3,656.28

The Association has a membership of 161 companies.

On motion of Mr. Radel of New Brunswick, N. J., the report of the Secretary and Treasurer was received and adopted.

The President—We will now take up the committee reports. The first paper is on "Comparative Earnings and Economy of Operation between Single and Double Truck Cars for City Use," by Richard McCulloch, Electrical Engineer Cass Avenue and Citizens' Street Railway Companies, St. Louis, Mo.

Mr. McCulloch read the paper, after which the President remarked that the paper was a very interesting and able one, dealing with a subject in which all were interested, and invited a discussion of it.

[The paper will be found elsewhere in this issue.]

The Secretary read a letter from Mr. Henry M. Watson, president of the Buffalo Railway Company, regretting his inability to be present at the meeting on account of sickness.

Mr. Kelly (Columbus)—It has been suggested that all the members of the Association who were present at the organization of the Association in Boston in 1882 will rise.

Messrs. W. Worth Bean, St. Joseph, Mich.; George B. Kerper, Dayton, O., and Julius E. Rugg, Boston, were the only members present who had attended the organization meeting.

After the Secretary announced that the special train for Lexington and Concord would leave at 2:30 P.M., and that at 8 o'clock there would be a reception in the Convention Hall, a motion for adjournment until 9:30 Wednesday morning was carried.

WEDNESDAY'S SESSION.

President Lang called the meeting to order at 10:30 A.M. and announced that the first paper of the session would be that on "Carrying of United States Mail Matter on Street Railways," by Mr. W. S. Dimmock, General Superintendent Omaha & Council Bluffs Railway & Bridge Company, Council Bluffs, Iowa.

Mr. Dimmock read the paper and a discussion on it followed in which Mr. Sargeant of Boston, Messrs. Beggs and Payne of Milwaukee, Mr. Farson of Chicago, Mr. Robert McCulloch of St. Louis, and Mr. Dimmock took part.

In his remarks Mr. Farson suggested that a committee be appointed, to act under the direction of the Executive Committee, for the purpose of obtaining from the different members such facts relative to street railway mail service as would enable the committee to present the matter in proper form to be brought before the postal authorities. A motion to this effect was put to vote and carried and the President announced that he would appoint the committee.

The President—We will now take up the next paper, "Maintenance and Equipment of Electric Cars for Street Railways," by Mr. M. S. Hopkins, Electrician Columbus Street Railway Company, Columbus, Ohio.

The Secretary read the paper, which was discussed by Mr. Sloan of Chicago, Mr. Hawken of Camden, Me., and Mr. McCormack of Brooklyn.

The President—Gentlemen, Mr. Caryl Ely, the First Vice-President of the Street Railway Association of the State of New York, has an invitation to extend to this Association, and he will now be given an opportunity of presenting it.

Mr. Ely—Mr. President and Gentlemen of the Association: The Annual Convention of the New York State Street Railway Association will be held at the Manhattan Beach Hotel next Tuesday and

Wednesday, and in behalf of that Association, and upon the suggestion of Mr. G. Tracy Rogers, its President, I take pleasure in presenting to you the invitation of that Association to such of you as may be able to do so to meet with that Association next week; and in that cool place, amid the singing of the murmuring waves, we may be able to get cooled off after the fatigues of this occasion.

Mr. Goff, Fall River—I move, Mr. President, that the thanks of the Association be extended to the New York Association, through Mr. Ely, for their very kind invitation to meet with them next week.

Carried.

The President—The Secretary has some communications in regard to the place for holding the next Convention.

The Secretary read letters from the Detroit Citizens' Street Railway Company, the Detroit Electric Railway Company and the Fort Wayne & Belle Isle Railway Company, Detroit, inviting the Association to meet in Detroit next year.

Mr. Holmes, Kansas City—I would like to introduce Col. Morse, who will extend an invitation to this Convention to hold its next meeting in Kansas City.

Col. Morse, of Kansas City, spoke of the advantage of that city as a place for holding the next Convention, and extended a most hearty invitation to the Association to meet there in 1899.

The President—These invitations will be received and referred to the Committee on Nominations for consideration. I will now name that committee: Mr. W. Worth Bean of Michigan, chairman; Mr. H. G. Hamilton of Missouri, Mr. E. C. Foster of Massachusetts, Mr. W. F. Kelly of Ohio, Mr. J. R. Chapman of Illinois, Mr. Henry C. Payne of Wisconsin, and Mr. E. H. Davis of Pennsylvania.

The Secretary announced that special cars would be in front of the Hotel Brunswick at 2 o'clock to take the delegates to the wharf to board the steamer at 2:30 P. M. for Nantasket Beach.

On motion of Mr. Kelly the Convention adjourned until 9:30 o'clock Thursday morning.

THURSDAY'S SESSION.

President Lang called the meeting to order at 10:30 A. M.

The President—The International Association of Factory Inspectors are now in session at the House of Representatives. It has been suggested that we send them an invitation to attend our sessions and to inspect the exhibits.

Mr. Robert McCulloch moved that such an invitation be sent and the motion was carried.

The President—We will now take up the first paper on this morning's programme, "To What Extent Should Street Railway Companies Engage in the Amusement Business," by Walton H. Holmes, general manager Metropolitan Street Railway Company, Kansas City, Mo.

Mr. Holmes read the paper. An interesting discussion followed, the speakers being Mr. Wyman of New Orleans, Mr. Davis of Williamsport, Mr. Holmes of Kansas City, Mr. John I. Beggs, Mr. Harrington of Camden, Mr. Farson, Mr. Claflin of Boston, Mr. Lang of Toledo, Mr. Chapman of Chicago, Mr. Thompson of Muskegon, Mr. Cahoon of Elmira, N. Y., Mr. Jones of Memphis and Mr. Heft of Meriden, Conn.

The President—We will now take up the report of the Nominating Committee.

Mr. W. Worth Bean, chairman, presented this report, as follows:

For President—Chas. S. Sergeant, 2d vice-president Boston Elevated Railway Co., Boston.

First Vice-President—Henry C. Moore, president Trenton Street Railway Co., Trenton, N. J.

Second Vice-President—Ernest Woodruff, president Atlanta Consolidated Street Railway Co., Atlanta, Ga.

Third Vice-President—Walton N. Holmes, general manager Kansas City Railway Co., Kansas City, Mo.

Secretary and Treasurer—Thomas C. Penington, treasurer Chicago City Railway Co., Chicago, Ill.

Executive Committee—Albion E. Lang, president Toledo Traction Co.; George E. Yuille, second vice-president West Chicago Street Railroad Co.; Frank Jones, president Memphis Street Railway Co.; John I. Beggs, general manager Milwaukee Railway and Light Co.; Ira McCormack, general superintendent Brooklyn Heights Railway Co.

Next place of meeting—Chicago, provided that facilities satisfactory to the Executive Committee as regards proper hall for Convention and exhibition purposes be furnished without expense to the Association.

On motion of Mr. Shaw of Boston the report of the committee was accepted, and the Secretary was authorized to cast the ballot of the Association for the gentlemen nominated as above, and they were officially declared the officers of the Association for the ensuing year.

Mr. Farson (Chicago)—May I not compliment the committee on this admirable report and the splendid selection of officers, and also upon their selection of Chicago for the next place of meeting. I may say on behalf of the street railway people of Chicago that we will do everything in our power to make the Convention interesting, profitable and instructive. We will welcome you, gentlemen, with open arms. (Applause.)

The President—I will appoint as the committee provided for in the motion regarding the carrying of United States mail matter on street railways the following gentlemen: John T. Burnett, Boston; Henry C. Payne, Milwaukee; Ira A. McCormack, New York; D. G. Hamilton, Chicago; W. S. Dimmock, Council Bluffs.

A letter from the Boston Elevated Railway Company, inviting the delegates to visit any or all of the various power plants, shops, car houses, etc., of the company, was read by the President. Other invitations were also presented, and letters of regret at inability to attend from Past President C. B. Holmes and Mr. D. B. Dyer of Augusta, Ga, were read.

The President—I have been informed that Mr. T. Y. Dzushi, Chief of Finance and Manager of Stores of the Imperial Government Railways of Japan, and Mr. K. Sugahara, Chief Engineer of the Kobu and of some street railroads soon to be built in Japan, are in the room, and have been attending this Convention since it opened, and I think that in some way we should express our pleasure in meeting them.

A motion by Mr. Ely that the privileges of the floor be extended to these gentlemen and that they be invited to address the Convention was carried.

Mr. Sugahara—Mr. President and Gentlemen: It is a great privilege and honor to have the pleasure of meeting you on this memorable occasion, and to occupy a seat in this National Convention of Street Railways in this great country. I desire to express my sincere gratitude for your hospitality extended to me as well as to my friend Mr. Dzushi. Japan is achieving a great deal in her material progress and is striving to accomplish in rapid succession what she learns from abroad. Your venerable Commodore Perry opened our gate toward Western civilization some forty-four years ago, and to-day your generous discoveries and inventions lead us hand in hand in the march of material civilization, for which we are greatly indebted to your people and country. I am naturally devoted to the investigation of street railway construction, and you can hardly imagine how interesting and helpful it is to me to be present in this great Convention.

The progress of our street railway system is very slow and it is in a primitive stage as yet. For instance, our street railways altogether are only about 60 miles in length and most of them depend on horse power, except the Kyoto and Nagoyo electric lines. Several electric railways, however, have been projected in different cities and towns throughout the country. We are firm in our belief that in the near future Japan will be found a network of electric street railways. Should I engage in Tokio street railways after returning home, and apply the knowledge I have gained here, I shall be very much indebted to you all and must pay cordial thanks. We have about 40,000 jinrikishas and 90 000 wagons drawn by men as means of transportation in Tokio, which greatly interferes with the progress of street railways. Notwithstanding these difficulties, Tokio horse car railway companies pay on the capital invested 30 per cent. dividends annually, and our steam road 13 per cent. We have no doubt that to build street railways in Tokio is one of the most promising enterprises. It is my great desire that our country shall progress in such a degree that when any of you shall come to Tokio you may go to any place in the city by street cars, not by jinrikisha, and that our country may be seen as one of the industrial countries of the world, and not alone a country of beauty and curiosity. Thanking you again for the kind privilege given us, and hoping you all may enjoy the blessings of health, liberty and prosperity, I beg to conclude my remarks.

The President—Gentlemen, I am sure that I express the feelings of all the members of this Association when I say that it is a great pleasure for us all to meet you. I take pleasure in presenting to you a badge that will admit you to all our sessions and every exhibit in the building, and I believe to every home in the city of Boston. I trust you will carry these with you with our best wishes. I also desire to present you with tickets to the banquet to-night, and we will be glad to have you join us at that time.

Mr. Dzushi—Gentlemen, it affords us great pleasure to meet you here. I desire to express our hearty thanks for your kind invitation.

Mr. Payne (Milwaukee)—I desire on my own behalf, and I have no doubt on behalf of all the members of the Association, to return to the members of the Massachusetts Street Railway Association and to members of the local committees, and all those who have interested themselves in entertaining us in the city, our sincere thanks for the magnificent manner in which they have done their work. I think it is not too much to say that the arrangements for this Convention have not been excelled in any place where we have met, certainly not where I have been in attendance upon the meeting. It is but proper that we should make known our feelings in that regard, and I offer a resolution that the Secretary be instructed to tender to these persons the heartfelt thanks and appreciation of the members of this Association.

Mr. Chapman seconded the motion, which was duly carried.

Mr. Payne (Milwaukee)—One thing more. I do not know whether it is the proper time, but I think the members of the Association will desire to place upon record their appreciation of the manner in which the officers during the last year have performed their duties, and I therefore desire to move that the thanks of the Association be tendered to the retiring President and the other members of the Executive Committee of the Association.

Mr. Payne put the motion, which was unanimously carried.

President Lang—I thank you very much, gentlemen, for this expression. We have only done our duty, and we hope the result of our labors will be beneficial to all who attended our meetings and all who may read the report of this meeting when published.

Mr. Ely (Niagara Falls)—I move that a special vote of thanks be extended to the members of the ladies' reception committee who have been so untiring in their efforts for the entertainment of the visiting ladies, and who have expended so much time and pains in making their stay pleasant here.

Carried.

The Secretary—I will announce the names of some new companies that have joined the Association since the opening of this meeting. They are: Warren, Brookfield & Spencer Street Railway Co., Warren, Mass.; Brockton, Bridgewater & Taunton Street Railway Co., Boston, Mass.; Providence & Taunton Street Railway Co., Taunton, Mass.; Milford, Holliston & Framingham Street Railway Co., Framingham, Mass.; South Chicago City Railway Company, Chicago, Ill.; St. Joseph Railway, Heat, Light & Power Company; Fair Haven & Westville Street Railway Co., New Haven, Conn.

The President—We will now have the paper on "Inspection and Testing of Motors and Car Equipments by Street Railway Companies," by Mr. Frederick D. Perkins, Electrical Engineer Toledo Traction Company, Toledo, Ohio.

Mr. Perkins was present, but owing to his indisposition the paper was read by the Secretary. On account of the lateness of the hour, the paper was on motion filed without discussion.

The President announced the trip to Plymouth in the afternoon, and the annual dinner in the evening, after which the meeting adjourned.

FRIDAY'S SESSION.

The President called the meeting to order at 10:40 A. M., and announced that the first business would be the paper on "Cost of Electric Power for Street Railways at Switchboard, both Steam and Water," by R. W. Conant, Electrical Engineer Boston Elevated Railroad Company, Boston, Mass.

Mr. Conant read the paper and was highly complimented by the President and by several of the delegates for the ability and labor he had expended in its preparation; but it was of such a nature that all thought its discussion at that time would do it an injustice.

The motion of Mr. Sergeant that the thanks of the Association be extended to the writers of all the papers presented at the meeting was then unanimously adopted.

The report of the Committee on Standard Rules for Government of Conductors and Motormen was incomplete, and an extension of time was granted the committee to formulate a set of rules to be submitted to the next Convention. The committee was also granted an allowance of $200 for the printing and mailing of the rules.

The President announced that it was the desire of the Secretary that members of the Association should indicate topics upon which it would be desirable to have papers prepared for the next Convention, and that they should also suggest a person who would prepare the paper.

The President—The only remaining thing for us to do is to install the newly elected officers, and the installation of the officers is usually represented by the installation of the President. I will appoint Mr. Chapman of Chicago and Mr. Davis of Williamsport a committee to escort the newly elected President to the chair.

The Secretary then read the names of all the officers elected.

The President—Gentlemen: It is needless for me to introduce Mr. Sergeant to you, but I desire to say that I appreciate the high honor you conferred upon me a year ago in electing me to this office, and I bespeak for Mr. Sergeant your kind and considerate attention to his communications. If you do as much for him as you have done to make this Boston meeting a success, we will have a splendid meeting at Chicago next year.

President-elect Sergeant—Gentlemen and Members of the American Street Railway Association: I wish to thank you most heartily for my most sudden elevation to office. I feel proud to be permitted to serve you for the coming year. I cannot hope, perhaps, to give as good an administration as my immediate predecessor, Mr. Lang, whose efforts in behalf of the Association I am sure you all appreciate, and the success which has crowned these efforts, and the long line of past Presidents, is one which fills the mind of a new incumbent with some embarrassment, based on the idea that there is a standard which must be upheld. As to this Association, I feel strongly that it has a great work to do, that its meetings are not merely a pleasant vacation, that it is not called together merely for the purpose of reading and discussing the papers, but I believe in the complex relations which are continually coming forward as between the committees and the municipalities and the State governments and street railways, that much is to be gained by concerted action. Certainly in Massachusetts we have benefited very greatly from the fact that our street railways have pulled together for what they knew was right, and they have succeeded after a struggle covering many years in obtaining a settlement which I suppose, looked at from all sides, could be called a fair settlement of the relations of the street railways and the community. I hope that the trial which is being made here of this new plan by which the oppressors of the street railways in a great many communities have been shown by an act of the Legislature how far the street railways are liable to perform work which is not in the line of street railway practice, and by which the street railways themselves are compelled to pay a portion of their receipts for the benefit of the highways—it seems to me that all this work which has been done is instructive and is the beginning of a proper recognition of our industry over the whole country. I assure you, gentlemen, when I first went into the street railway business, particularly in the operating department, I was perfectly appalled; it seemed to me I was in an unlawful business, and everybody was down on the street railway, for it was hampered and troubled by one requirement and exaction after another, and when we made complaints the answer to it all was, "You are in the public streets, you encumber the streets, and you must pay for it." How much better it is to know what we have to pay for, than it is to be put to such payment that may devolve upon us in the judgment of some subordinate road department official in some municipality. I think in such ways as that, and in this matter which was taken up the other day, of the mail service, simply in having our case presented in order to get proper recognition, the Association has a field perhaps greater than any it has yet filled, and I can only say in closing that so far as it lies in my power to further the work of the Association and benefit the interests of street railways, I shall certainly do so. I thank you very much, gentlemen, for the honor.

Ex-President Lang—I now declare the newly elected officers to be duly installed, and take pleasure in handing to the new presiding officer the gavel, with my best wishes. (Applause.)

President Sergeant—I believe that the constitution of our Association provides that the newly elected officers shall enter upon their duties after the annual meeting is adjourned, and as it seems almost as if some duties were about to be forced upon me, I suppose for that reason a motion to adjourn would be in order.

Mr. Goff (Fall River)—I move you, Mr. President, that we now adjourn to meet in Chicago in 1899.

The motion was adopted and the Convention adjourned.

Besides the regular delegates there were present at the Convention as many as 134 non-members, representing the leading street railway and manufacturing interests of the country. The attendance of ladies was unusually large, there being in all about 200, hailing from widely scattered localities such as Buffalo, Chicago, New York, Cleveland, Detroit, Kansas City, Memphis, Philadelphia, and even Liverpool, England.

The exhibits were numerous and were of the usual character. The supplyman was present in greater force than ever before, there being between five and six hundred men present interested in the diffusion of electrical and kindred appliances.

DELEGATES AT THE CONVENTION.

Allentown, Pa.—A. F. Walter, sec. and treas., and Jilson J. Coleman, director, Allentown & Lehigh Valley Traction Co.

Alton, Ill.—J. F. Porter, pres., and H. H. Harrison, elec., Alton Railway & Illuminating Co.

Atlanta, Ga.—E. Woodruff, pres., J. Carroll Payne, vice-pres., Thomas Elliott, chief eng., and N. W. L. Brown, elec., Atlanta Consolidated Street Railway Co.

Baltimore, Md.—P. O. Heilholtz, elec. eng., J. M. Christopher, mast. mech., and D. E. Evans, Baltimore Consolidated Railway Co.

Battle Creek, Mich.—L. N. Downs, pres., E. Hope Norton, vice-pres., Dee Allen, sec., and Fred. I. Griswold, gen. man., Michigan Traction Co.

Bay City, Mich.—W. R. Morrison, asst. gen. man., and R. S. Ashe, supt., Bay Cities Consolidated Street Railway Co.

Binghamton, N. Y.—G. Tracy Rogers, pres., J. P. E. Clark, man., Binghamton Railroad Co.

Boston, Mass.—William A. Bancroft, vice-pres., Charles S. Sergeant, second vice-pres., R. H. Derrah, executive clerk, J. H. Goodspeed, compt., J. E. Rugg, supt. of transportation, John Balch and Chas. H. Bigelow, eng. dept., Boston Elevated Railway Co.

Bridgeport, Conn.—Andrew Radel, pres., and George H. Sanford, counsel, Bridgeport Traction Co.

Brockton, Mass.—Horace B. Rogers, gen. man., and John P. Morse, director, Brockton Street Railway Co.; A. C. Ralph, supt., A. B. Williams and P. W. Sprague, Brockton, Bridgewater & Taunton Street Railway Co.

Brooklyn, N. Y.—Clinton L. Rossiter, pres., Ira A. McCormack, gen. supt., and J. H. Vanderveer, supt. motor dept., Brooklyn Heights Railroad Co.; M. W. Conway, contractor, Brooklyn City & Newtown Railroad Co.; Albert L. Johnson, pres., Wm. F. Ham, sec. and Frank S. Drake, gen. supt., Nassau Railroad Co.

Buffalo, N. Y.—George Chambers, supt., Buffalo Traction Co.; Robert Dunning, mast. mech., and R. E. Danforth, supt., Buffalo Railway Co.

Butte, Mont.—Jesse R. Wharton, Butte Consolidated Railway Co.

Camden, N. J.—George Browning, treas., and Walter E. Harrington, gen. man., Camden & Suburban Railway Co.

Charleston, S. C.—F. D. McEowen, sec. and treas., T. W. Passailaique, gen. supt., and A. S. Boyer, director, Charleston City Railway Co.

Chicago, Ill.—John Farson, pres., and H. M. Sloan, gen. man., Calumet Electric Railway Co.; T. C. Penington, treas., Frank R. Greene, sec., G. W. Knox, elec. eng., C. J. Reilly, chief eng., A. C. Heidelberg, asst. supt., Charles E. Moore, mast. mech., Walter V. Penington, clerk, J. J. O'Keefe and G. O. Nagle, Chicago City Railway Co.; John M. Roach, second vice-pres. and man., James R. Chapman, man. elec. dept., and John Miller, mast. mech., North Chicago Street Railroad Co.; George A. Yuille, asst. gen. man., and W. Frank Carr, engineer, West Chicago Street Railroad Co.

Cincinnati, O.—Bert L. Kilgour, elec., Cincinnati Street Railway Co.

Cleveland, O.—John Ehrhardt, asst. sec., Cleveland City Railway Co.; H. J. Davies, asst. sec. and treas., and W. G. McDole, aud., Cleveland Electric Railway Co.

Colorado Springs, Col.—A. L. Lawton, gen. man., Colorado Springs Rapid Transit Railway Co.

Columbus, O.—W. F. Kelly, gen. supt., and P. V. Burington, aud., Columbus Street Railway Co.

Council Bluffs, Ia.—W. S. Dimock, gen. supt., Omaha and Council Bluffs Railway & Bridge Co.

Dayton, O.—George B. Kerper, gen. man., George B. Kerper, Jr., asst. gen. man., People's Railway Co.

Derby, Conn.—H. Holton Wood, pres., B. W. Porter, gen. man., and W. J. Clark, Derby Street Railway Co.

Detroit, Mich.—T. C. Hutchins, vice-pres., Detroit Citizens' Street Railway Co.

Elmira, N. Y.—J. B. Cahoon, gen. man., Elmira & Horseheads Railway Co.

Findlay, O.—Charles D. Kinney, treas., and Chas. F. Smith, supt., Findlay Street Railway Co.

Fall River, Mass.—Robert H. Goff, pres. and man., H. Read, treas., J. H. Bowker, supt., and G. W. Palmer, Jr., elec. eng., Globe Street Railway Co.

Galveston, Tex.—F. W. Pratt, supt. and eng., Galveston City Railroad Co.

Girardville, Pa.—E. W. Ash, gen. man., and C. A. Bragg, director, Schuylkill Traction Co.

Gloucester, Mass.—W. B. Ferguson, pres., Gloucester Street Railway Co.

Hamilton, Ont.—V. H. Wagoner, elec. and mech. eng., and J. F. Little, Hamilton Street Railway Co.

Harrisburg, Pa.—F. B. Musser, supt., Mason D. Pratt, eng., Harrisburg Traction Co.

Hartford, Conn.—E. S. Goodrich, pres., Elmer M.

White, cashier, Hartford Street Railway Co.

Hazleton, Pa.—A. Markle, gen. man., and G. W. Thompson, supt., Lehigh Traction Co.

Youngstown, Ohio.—A. A. Anderson, gen. man., Mahoning Valley Railway Co.

Convention of Street Railway Accountants.

The Street Railway Accountants' Association of America held their annual meeting in Boston, September 6-9, contemporaneously with that of the Street Railway Association. The President, H. L. Wilson, in his annual address spoke of the importance of the auditing department in the management of any street railway company's business, and referred in terms of commendation to the work his Association's committee had done toward establishing a standard system of accounts and statistical work, seeking and following out suggestions from many organizations and corporations regarding their methods, and shaping these into a simple yet comprehensive form for the benefit of the Association. He said that valuableinformation had been secured and a system which is comprehensive and of broad scope to be applied to the business of large or small street railway companies had been the careful study of the committee. He said that the membership of the Association is gaining in strength, and wide-spreading territory was being represented.

In the Secretary's report it was shown that the Association now embraces sixty-eight different street railway companies, representing various parts of the United States, and including Canada, Mexico and the Hawaiian Islands.

The papers read were principally on subjects connected with the auditor's vocation.

An Electric Foundry.

A special to the New York *Commercial* from Reading, Pa., says:

"The new electric appliances that run the Reading Car Wheel Works have been given a fair trial, and the results are more than satisfactory to the firm. This is the first electrical equipment ever installed in a foundry, and was introduced with the belief that it would be more economical in cost and much more convenient than steam. The current is taken from the Metropolitan Company's wires, and thus far the system has worked well. The system covers everything that steam can run and is very complete.

"Several times when the bottom of the cupola has been dropped the motor has been splashed with molten iron, but this occasioned no trouble. Motors run the elevator and the drop used for breaking old car wheels. This drop has a fall of 40 feet. The ladel carriers have a capacity of about 800 pounds to the floors. These ladels are operated by a small reversing motor which can be run by the man in charge of the large pouring ladel. The five-ton ladel is run by a motor in the rear. All the carriages over the tracks are operated by electric motors.

"All motors are specially built to stand a temperature of 150 degrees. They are equipped to reverse at varying speed. From each controller is run a hand rope to the floor, so that each molder has a perfect control of the speed and can vary it from one to fifty feet per minute on the hoist. Each hoisting motor has an electric brake. By electric power the red-hot car wheels are lifted from their molds and taken to the annealing pits. The system enables the men to work rapidly and at less cost than before. The tumbling barrels and pressure blowers are also run by motors."

There has been a great deal said in newspapers lately about the discontinuance of "The Lake Shore Limited," the New York Central's twenty-four hour train between New York and Chicago.

There is no truth in this rumor. "The Lake Shore Limited" will continue to run every day in the year over the New York Central & Hudson River, and Lake Shore & Michigan Southern Railroads—the same tracks that carried the Exposition Flyer, between New York and Chicago, in twenty hours, for 175 days during the World's Fair.

COMPARATIVE EARNINGS AND ECONOMY OF OPERATION BETWEEN SINGLE AND DOUBLE TRUCK CARS FOR CITY USE.*

BY RICHARD M'CULLOCH.

Before beginning a discussion of this subject, it would be well to define what is meant by single and double truck cars, as these terms are often very loosely used. In this paper a single-truck car will mean one in which the body rests upon a truck, the axles of which are parallel with one another, and at all times perpendicular to the center line of the car. In a double-truck car the body is pivoted upon two independent trucks, each of which swings underneath the body with perfect freedom.

Double trucks for electric cars are of comparatively recent adoption. All of the early electric cars were equipped with single trucks, and in this horse car and cable car practice was followed. As the single truck was first on the ground, and at present largely has possession of the field, it will be assumed that in this case of the double truck versus the single truck, the double truck is the plaintiff and must submit the weight of the evidence.

Double trucks were first applied to cars in the desire to use longer bodies than had been customary. In the use of a single truck the best practice has been to limit the wheel base to about 7 ft., as a greater distance than this would cause the wheels to bind in curves. Assuming that the body of the car is 20 ft. long and that the platforms project 4 ft. beyond the body, the end of the platform would overhang the axle 10.5 ft. This is as great an overhanging as is customary, although single-truck cars have been built with bodies longer than 20 ft. In this case it is necessary to provide extension springs on the trucks to check the oscillation of the car body. With a very long car body, however, the oscillation is not entirely overcome by this device, and the rocking becomes very disagreeable to passengers and very disastrous to the car and track. Twenty-two feet may be arbitrarily established as the limiting length of the body of a single-truck car, and if we wish to use car bodies longer than this, we must adopt some truck which will avoid oscillation, and which will pass around curves without undue use of power. The double truck accomplishes this, and it was to enable longer bodies to be used that it first came into use.

The truck which was first used for long street railway cars was an adaptation of that used by the steam railroads. This truck contains four wheels of equal size and is pivoted over the center. It was soon discovered that for street railway uses this form of truck had two very objectionable features, first, that the floor of the car must be high enough above the rail to allow the wheels to swing freely under the car, and secondly, the motor being geared to one axle of the truck, only 50 per cent. of the weight of the car was available for traction. The latter is a serious objection on roads having grades.

From what has been said it will appear that the single truck is the truck for short cars, and the double truck is the truck for long cars. Therefore, a discussion of the relative merits of these two types of trucks will involve a discussion as to the relative merits of short and long cars. Also, as it is customary to supply long cars with cross seats and short cars with longitudinal seats, we have instead of the comparatively simple subject of single trucks versus double trucks, which has been assigned to your committee, the more complicated struggle between the short car with single trucks and longitudinal seats, and the long car with double trucks and cross seats.

It will be assumed in the discussion which follows that the road possesses the characteristic city travel (a load curve of which was shown).

* Read at the Convention of the American Street Railway Association, Boston, Sept. 6-9, 1898.

It will be noted that two very pronounced peaks occur in this load curve, one in the morning from six to nine and the other in the evening from five to seven. It is at these times that the capacity of everything is tried. While the load curves of all city roads resemble each other, it is evident that local conditions will to a large extent determine the kind of car which the railroad company will operate. Some of these local conditions are the class of people who constitute the passengers, the location of the road with reference to the established lines of travel, the amount of pleasure travel received by the road, and the keenness of competition with other roads. The last is an important condition, because a road is sometimes forced to adopt certain measures for its protection which it would not adopt under any other consideration. In this discussion we will assume that it is to the interest of the road, even if no immediate competition exists, to use all reasonable endeavors to please its patrons, because this policy will render the road more ready to meet competition when it arrives.

Before the advent of the electric car, the horse car had become such an established institution in this country that certain standards as to track and rolling stock had become fixed. In the matter of rolling stock, the size of the car had always been limited by the ability of two horses to draw it. When a mechanical motive power replaced the horses this limit disappeared, and almost the first improvement made in rolling stock was to increase the size of car bodies. Instead of bodies 16 ft. long, electric cars were built with bodies 20 ft. long, and now this length is being increased to 28 ft. and 30 ft.

The expense of the average city road may be divided up as follows:

Maintenance of way and structures	4 per cent.
Maintenance of equipment	7 per cent.
Conducting transportation	52 per cent.
General expense	8 per cent.
Fixed charges	29 per cent.

It will be noticed that the item "conducting transportation" is more than one-half of the total. This is largely made up of the wages of conductors and motormen, and is proportional to the number of cars operated. Hence it follows that if we may by the operation of larger cars cut down the number of cars, this account may be reduced in nearly the same ratio as the size of the car is increased. There are many other reasons why the size of the cars has been increased, such as the increased volume of traffic due to the higher speed and enlarged territory of the street railroads, the greater comfort demanded by the traveling public, the increased power available for the operation of cars, etc., but it is probable that the present tendency toward the increased size of car bodies is with a view of operating larger units and fewer of them.

A line operating small cars seating twenty-eight persons on a headway of $3\frac{1}{2}$ minutes would give the same service from a standpoint of seating capacity if it operated large cars seating forty persons on a headway of five minutes. Manifestly, this latter service would be preferable from the railroad standpoint for the reason just given, and the question is, would the service be equally acceptable to the passenger? In this comparison we are assuming that the larger car is the more desirable vehicle in which to ride. Would the pleasure of the ride compensate the passenger for the greater length of time which he would have to wait? This is a question which must be solved by each manager for his particular road, as its correct solution depends largely upon local conditions over which he has no control. The scrutiny with which a passenger chooses a street car varies with the length of his proposed ride. If the ride is to be short, he takes the nearest car without reference to comfort; but if he is to ride a long distance, he will walk past several lines in order to choose that one on which he will have the most pleasant ride. The car question then becomes a more serious one with long roads and with roads catering to a pleasure traffic. It has usually been accepted that on those having a purely business traffic the proper car is the short one operated on short headway. The author, however, is of the opinion that even in this case the long car operated upon somewhat longer intervals would be desirable. It has often been observed that where a line operates two sets of cars a passenger will allow several cars to pass him in order to patronize that type of car which suits him best. This has been observed even in the busy hours of night and morning when it would be fair to assume that passengers would be hurried and likely to take the first car which passes.

One of the most serious questions occurring in street railway practice is the problem of how to take care of the rush travel which comes morning and evening. With our present methods there are only two ways of taking care of this travel: the first, by increasing the number of cars or units in service; and the second, by increasing the capacity of each unit. The latter method consists of attaching a trailer to the motor car, and where this is done it is usual, also, to increase the number of units in service. On first thought there would seem to be no better method of increasing the capacity of the road than by the use of trail cars. They are easily attached and detached; they are in service only when necessary, and they do not require the assistance of additional trainmen. An examination of the trailer system, however, will reveal the fact that it possesses serious defects. The trailer is not automobile, and requires the services of men and horses to attach it to the cars and to move it between the car sheds and the motor cars. The opening between the motor and trail car increases the danger of accident to both passengers and conductors. The number of entrances and exits is increased, and this augments the work of the conductor in keeping track of his fares and increases the danger of his missing some of them. If an extra conductor is placed on the trailer to collect fares, a great portion of the gain due to the trailer system is lost. The use of trailers throws an additional strain on the motors, as a heavy weight is added to the train which is not available for traction. The trouble is intensified as the load on the trailer increases; it makes the train more unwieldy in handling, and is largely responsible for the difficulty in starting and stopping quickly and in making schedule time.

To obviate the necessity of using trailers, a large car equal in seating capacity to the combined capacity of the motor and trail car may be operated. This system, however, introduces the disadvantage of the operation at all times of the day of a seating capacity needed only during a few hours of the day. It also increases the size and weight of the cars and the average power required to operate them.

In order to compare the relative economies of single and double truck cars, their advantages and disadvantages will be discussed with reference to the following points:

1. Wear and tear on trucks.
2. Wear and tear on motors.
3. Power required.
4. Wear and tear on track.
5. The use of trailers.
6. The seating arrangements and convenience of exit and entrance.
7. The preferences of passengers.

These relations will, as far as possible, be reduced to a money basis, and in order to do so a comparison will be instituted between a road which operates double-truck cars and one operating single-truck cars using trailers 26 per cent. of the time to take care of the heavy night and morning travel.

The bodies of the double-truck cars are 26 ft. in length and contain eighteen cross seats, seating 36 passengers. The trucks are of the maximum traction type; the empty car weighs 23,500 lbs., and the motors are G. E. 800.

The single-truck car has a body 20 ft. in length;

it is equipped with longitudinal seats and the entire car weighs 16,000 lbs. It will seat 28 passengers. During the period of heavy travel, which amounts to 26 per cent. of the time, trailers are attached to these motor cars. Open trailers are operated in the summer months and closed trailers during the winter. The average seating capacity of the unit, estimating the trailer as a part of the car during the time that it is operated, is 35 seats, which approximates the seating capacity of the double truck cars very closely. The motors in use on the single-truck cars are W. P. 50.

The number of cars operated is obtained by dividing the daily car mileage by 115. It is necessary to do this because the average mileage per car on the two roads is different. The comparison is thus between 70 single-truck cars and 47 double-truck cars, each car making 115 miles per day. The road operating the double-truck cars has the greater density of traffic.

WEAR AND TEAR ON TRUCKS.

It is evident that since a car equipped with double trucks has eight wheels and one equipped with single trucks has four, the former will be more expensive to supply with wheels. Table I shows the comparative replacement and cost of wheels and brake shoes on the two roads for one year. Table II shows the comparative cost of maintenance and repairs of trucks and motors for two years. It will be noted that while the cost per car is much greater on the road using double trucks the cost per passenger is almost the same. It would not be fair to assume from these figures that the cost of maintenance of trucks and motors per passenger is always the same no matter what sort of truck is used, because these figures result largely from the fact that in this particular case the double-truck car carries the greater number of passengers, but an inspection of the table will emphasize the advantage of the large unit as compared with the small one. It will be seen by reference to Table I that the greater part of the increased expense of maintaining the double-truck is due to the renewals of wheels and brake shoes.

In examining the relative strength of the various parts of trucks the side pieces may be compared to a beam supported at two points and carrying a concentrated load. The deflection of such a beam is proportional to the third power of the span, and in the analogy the span corresponds to the wheel base of the truck. Therefore, the shorter the wheel base the stiffer the truck side, and in view of its long wheel bases it is evident that the single truck is at a disadvantage in this respect. For instance, a truck side where the wheel base is 4 ft. 6 in., is 3.76 times stiffer than a truck side of equal section where the wheel base is 7 ft.

WEAR AND TEAR ON MOTORS.

Table II, to which reference has been made, gives the comparative expense of inspecting, repairing and maintaining the motors of double and single truck cars. As in the case of the trucks, it will be noted that while the expense per car is much greater in the case of the double-truck car, the expense per passenger is nearly the same.

Table IV gives the relative weights carried by the different cars, when empty, seats full and car crowded. It will be noted that while the percentage of weight available for traction in the case of the maximum traction truck remains constant, in the case of the motor and trailer it falls off as the number of passengers increases, and is especially small if the trailer is proportionately more heavily loaded than the motor car.

POWER REQUIRED.

Table III gives the power required to operate the different cars, and is the average of a long series of wattmeter tests. In making these tests the wattmeter was placed on a car in actual service and allowed to remain through the entire day. An examination of the tables will reveal the fact that the power required for the propulsion of the car and the care and repairs which the motors demand are much greater in the case of the double-truck car. But if the number of passengers be taken into account, it is seen that the power and the cost of maintenance are roughly proportional to the number of passengers carried with either style of truck.

WEAR AND TEAR ON TRACK.

The wear of the rails of a street railway track is due to the grinding action of the wheel on the rail, and this is proportional to the weight on the wheel, but is intensified by the dirt on the rail, which causes the wheel to slip and act as an abrasive agent after the slipping has begun. The weak point of a street railway track, however, consists of the joints and the opening in the special work. The energy of the blow which the wheel strikes as it passes a low joint or a crossing is equal to the product of the weight of the wheel and the height of the drop. Therefore, on any given track both the wearing action of the wheel and the destructive action of the wheel are proportional to the weight which rests upon it. If the number of wheels under a car be increased, the number of blows which a low joint receives is also increased, but the intensity of each blow is diminished. Double trucks are at no disadvantage as compared with single trucks in this respect, unless the weight of the car be increased. Due to the shorter wheel base, double trucks go around sharper curves and go around the same curve with less output of power and less wear on the rail than single trucks. The double truck fell into disrepute when the maximum traction truck was first exploited, on account of its liability to leave the track. This was due to the small amount of weight which was placed on the small wheels. It is now customary to place 30 per cent. of the weight on the small wheels, and with track in fairly good condition, no difficulty is encountered in keeping cars on the track.

THE USE OF TRAILERS.

In the case of the two roads under discussion, the road operating single-truck cars attaches trail cars to the motor car for two trips in the morning and two trips in the afternoon. For the entire year trailers were operated on 26 per cent. of the trips. Allusion has already been made to the use of trailers. The advantage of the trailer on this particular road arises from the fact that the load peaks are unusually sharp. The use of the trailer increases the capacity of each unit during the heavy hours of morning and evening travel and during rush hours due to base-

TABLE I.

Comparison of the cost of wheels and brake shoes on double and single truck cars for the year 1897.

	Average number wheels used per car per year.			Cost per car per year.				Total cost per car per year per 1,000 passengers.	Wheel mileage.	
	33″	30″ trailer.	24″	Wheels.	Labor in replacing.	Brake shoes.	Total.		33″	24″
Double truck cars (47)......	8.72	......	7.06	$77.92	$17.36	$11.70	$106.98	$0.47	17260	20916
Single truck cars (70)......	6.26	1.00	......	40.43	7.99	4.80	53.22	0.38	25329	......

The double truck car has four 33-in. wheels, four 24-in. wheels and eight brake shoes. The single truck car has four 33-in. wheels and four brake shoes. Average daily car mileage—115.

TABLE II.

Comparison of the cost of repairs and maintenance of trucks and motors on double and single truck cars for the years 1896 and 1897.

	Average passengers per car per year.	Truck repairs.		Motor repairs.		Total.	
		Per car per year.	Per car per year per 1000 passengers.	Per car per year.	Per car per year per 1000 passengers.	Per car per year.	Per car per year per 1000 passengers.
Double truck cars (47)......	226,000	$181.00	$0.80	$319.00	$1.41	$500	$2.21
Single truck cars (70)......	141,000	110.00	0.78	196.00	1.39	306	2.17

G. E. 800 motors on double truck cars. W. B. 50 motors on single truck cars.

TABLE III.

Comparison of the power required by double truck and single truck cars.

	Average watts.	Average watt-hours per car mile	Average speed miles per hour.	Average watts per seat capacity.	Average watts per ton, car empty.	Average watt-hours per car mile per 1000 passengers.
Double truck car—seats 36, weight 11.75 tons.						
Average for the entire day	12040	1334	9.03	335	1025	5.9
Average for the heaviest trip	13080	1412	9.25	335	1025	......
Single truck car—no trailer, seats 28, weight 8 tons	8471	921	9.20	3.3	1060	......
Single truck car—trailers operated 26 per cent. of the time.						
Average for the entire day	9400	1110	8.42	254	1088	7.9
Single truck motor and open trailer—seats 63, weight 10.5 tons.						
Average for the heaviest trip	12680	1410	8.84	201	1208	......

TABLE IV.

Comparison of weights carried by single and double truck cars.

	Number of seats.	Total crowded capacity.	Weight empty.	Percentage of weight on driving wheels.			Pounds weight per cent.			Pounds weight per unit of total capacity.		
				Car empty.	Seats full.	Car crowded.	Car empty.	Seats full.	Car crowded.	Car empty.	Seats full.	Car crowded.
Single truck motor car........	28	80	16000	100	100	100	572	702	943	200	246	330
Single truck motor car with open trailer........	63	140	21000	76	67	67	334	463	622	170	210	280
Single truck motor car with closed trailer........	48	125	21000	76	72	71	438	568	776	168	218	298
Double track car........	36	1.0	23500	70	70	70	653	782	1,050	214	258	344

Each passenger is estimated at 130 pounds.

ball games and races. On this particular road the motormen and conductors are paid ten cents per trip extra for all trips where a trailer is attached to the motor car. This expense largely offsets the value of this arrangement. There is no question but that the use of the trail car increases the number of accidents, for two reasons: first, because the trailer is another car, and second, because the opening between the motor and trail car is a dangerous one for a passenger boarding or alighting from the car. It is impossible to estimate the money value of this accident liability, because in the case of many accidents it is difficult to determine what proportion of the damage was due to the trailer. Trailers must be switched at the ends of the roads and at the car sheds and require men and horses for this purpose. The use of trailers also entails other expenses, such as car heating, cleaning, repairing and car license, which should be charged against the trail car system. To counterbalance all these disadvantages, the only advantage which the trail car system possesses is its flexibility.

THE SEATING ARRANGEMENTS, EXITS AND ENTRANCES.

As has already been stated, the cross-seat is used almost so universally in connection with the double-truck car that it is fair to consider the economy and efficiency of cross-seats and longitudinal seats in connection with the discussion. There is no doubt that the cross-seat is preferable from the passenger's standpoint, and the reasons for this preference are not difficult to analyze. Passengers often travel in pairs, and the cross seat gives a privacy to their conversation which is not possible with the longitudinal seat, the jerks due to the stopping and starting of the car are less disturbing to the passenger when he is seated facing the direction of motion, and the cross-seat renders it easier to look out of the windows.

If two car bodies of the same size are taken and cross-seats installed in one and longitudinal seats in the other, the car body equipped with the cross seats will have the narrower aisle. This induces two disadvantages in the cross-seat; one, that the crowded capacity of the car is less, and the other, that when the car is crowded the time consumed in loading and unloading is increased. The latter difficulty will be the more serious the shorter the haul and greater the number of stops.

In the early days of the double-truck car, it was customary to mount the body high enough so that the wheels would swing under it. This gave the car a very unsightly appearance and made it difficult of access. Three steps were necessary to reach the platform, and as these steps were steep, this form of car was particularly objectionable to ladies. By the use of the maximum traction truck with 33-in. wheels, however, it is possible to lower the floor to within 37 in. of the rail. By dropping the platform 8 in. below the floor of the car, it is possible to reach the platform by the use of a single step 14 in. above the rail. This renders the car as easy of access as the single-truck car. In the opinion of the writer, the fact that the car floor may be made so low in double-truck cars is the chief advantage of the maximum traction truck.

It has been attempted to facilitate the loading and unloading of large cars by providing exits and entrances other than the rear door. This practice, however, brings about what is perhaps a more serious disadvantage, as it gives the conductor more than one door to watch, renders it difficult for him to keep track of his fares, and increases the liability of his starting the car before a passenger is on or off.

THE PREFERENCE OF PASSENGERS.

The preference of passengers, to which allusion has already been made, is undoubtedly in favor of the double-truck car. In cities where the entire street railroad system is controlled by one company, this point may not be considered of value, because passengers are obliged to ride in whatever conveyance the company chooses to furnish. However, the experience of roads which have changed their rolling stock from small single-truck cars to large, comfortable double-truck cars, is that the travel has shown an immediate increase. Part of this increase has been drawn from parallel roads, but part has been a created traffic. As the accommodations increase, more people ride, and the regular patrons ride oftener. The street car ride instead of being regarded as a necessary evil, comes to be looked upon as a pleasant part of the shopping expedition, the visit, or the picnic. How great this created traffic will be depends upon the class of patrons served by the road and upon the terminal facilities of the line. The extremes of society, the very rich and the very poor, are not good riders, and it is probable that a road serving either of these classes entirely would get very little return for additional accommodations. The greatest increase would come from those who are now the best patrons of the street railroads, the fairly well-to-do middle class.

In this paper the writer has not attempted to prove that either the single truck or the double truck car is the better type. He has merely attempted to discuss the subject to bring out the strong points and the weak points of each type in such a way that the results may be applied to special and local conditions. Outside of the question of economy of operation, there are few roads on which the use of attractive, easy-riding, double-truck cars would not create travel, especially in the summer season. In a general way it may be stated that the single-truck car is more suitable for short hauls, dense traffic, many stops and low speed. On the other hand, the double-truck car is more suitable for long hauls, high speed, few stops and pleasure travel. In the existence of either extreme condition, it would not be difficult to decide which car to use. It is in dealing with intermediate conditions that the manager must use his judgment.

DISCUSSION.

Mr. McCormack (Brooklyn)—Mr. McCulloch states in the paper that with the use of double-truck cars it would be possible to lengthen out the headway. I wish to state that on our heavy lines we have had between three and four hundred double-truck cars and in not a single instance have we been able to lengthen out the headway. The double-truck cars increase the patronage to such an extent that we have had to shorten the headway. One thing more, and that is when it comes down to standing loads and moving crowds; yesterday (Labor Day) I noticed on the cars seating 40 passengers going to Coney Island that the average was 65 on the register. With a double-truck car, and a seating capacity of 60, it is nothing unusual to see 128 and 130 on the register, so you can see when you want to move large crowds what the difference is with the double-truck car compared with a single-truck car. There are 178 double-truck cars running in the service on one line and you can imagine what the travel is on that line.

Mr. Dimmock (Council Bluffs)—What is the headway?

Mr. McCormack—The headway on the Court street line, running from New York direct to Coney Island, is less than a minute. On the Third avenue line it is three minutes nearly all day, and part of the time two minutes. The headway from 65th street to Coney Island, where all the Coney Island cars converge, is about twenty seconds.

Mr. Sloan (Chicago)—The double-truck cars are certainly coming into practice and favor, and it seems to me the main question is the question of traction. I have had no experience with double-truck cars, and I would like to know whether anyone who has had experience with them knows anything about the motors, using four motors instead of two, to get the maximum traction. It is a subject we should know more about, because in the use of the double-truck cars we are replacing the two motors with four.

Mr. Beggs (Milwaukee)—I think Mr. McCulloch has so thoroughly presented the case that there is very little to be said upon it, particularly in behalf of the "plaintiff." I do not think that the writer of the paper evinced any partiality as between a single and double truck car; but it is very evident in what direction the sympathies of the writer of the paper lie. In the city of Milwaukee we have for three years been experimenting practically with the advantages and disadvantages of single and double truck cars. In 1896 there was put upon the system twenty double-truck cars with Maxim trucks. These cars were equipped with 18 double seats, seating 36 persons. A year ago, the early part of 1897, in view of our experience of a year in the use of the cars, we enlarged somewhat upon them, improved the trucks to some extent, we thought, by abandoning the Maxim truck and so building the frame of the car as to in that way obviate what had been with us a very serious difficulty, namely, the forward wheels leaving the rail. We use 30-inch wheels to accomplish it. We increase the length of the car and seat 40 passengers by placing in double seats. During the present year we have been benefited by our experience still further, and increased the length of the car, that is, the body, and enlarged the seating capacity without at all increasing the overall length, which is 41 feet over bumpers, and maintain virtually the same size of platform so far as the accommodation to passengers is concerned, in crowds, by increasing the length of the body one foot, slightly moving the seats together and reducing the amount of the bumper in front of the dash; so that with our present car, so far as our service is concerned, there is little left to be improved upon. We seat 44 passengers, having 22 double seats.

Of course the question as to the use of the double-truck car is determined by local conditions. Our double-truck cars, for the climate of Milwaukee, are to a great extent a necessity. Because of the large open spaces and our short summer season, it is almost impracticable to maintain the duplicate equipment necessary for summer and winter services. I do not know anyone now in the service of the company who has not been converted to the use of the double-truck car, and we have arrived at a standard. There are many reasons existing for the adoption of a standard car with us—the short summer season, the likelihood of chilling winds coming up and cold rains at any time in the warmest days of summer. We now have a car that suits us twelve months in the year. We have not had any difficulty with the matter of traction. We use a 33-inch wheel in the equipment we are having built and still maintain only a distance of 32 inches from the rail to the bottom of the sill; and that was one of the difficulties we had to overcome. We did that by giving considerable attention to the matter of the construction and framing of the car to permit the 33-inch wheel to readily pass around our shortest curves. We are so thoroughly convinced as to the advantages of the double-truck car that we are gradually permitting all our single-truck cars to be worn out and scrapped as their life is brought to an end.

We have found that the use of the double-truck cars has greatly increased the traffic; in other words, the people would wait for double-truck cars on certain lines. We are compelled to place some of the single equipment on at times, but the people still wait on the streets where the two types of cars are run on the same lines for the double-truck car, for the reason that the riding is much more comfortable. The double-truck cars on our lines ride almost as smooth as a Pullman sleeper. That, of course, depends largely on the character of the track; but on a large portion of our lines, particularly on those lines where we are putting on the heavy equipment, we are having the connection between the rails cast-

welded at the joints, and we are doing away with the rocking and pitching motion of the car, and are enabled by the use of the double-truck to make much higher speed, and that is the tendency of roads all over the country. We have to make higher speeds. We brought our average up within two years certainly a mile an hour. Our average speed now is somewhat in excess of nine miles per hour. We would not be able to do that with a single-truck car, because of the oscillating motion and the liability of the pitching to displace the trolley wheel, whereas with the double-truck cars we seldom have such an experience.

As to the matter of wear and tear, we believe the weight of evidence is in favor of the double-truck car. While we have double the number of trucks and double the number of wheels to maintain, the blow on the wheel at crossings and special work is so much easier that it does not wear the tracks nearly so much, and we find that our repairs of springs is possibly 75 per cent. less on the double-truck cars than on the single-truck cars. We have been able on our lines—and I, of course, recognize the difference of conditions between Greater New York and our less populous cities—been able to increase our headway on most of the lines on which we have placed double-truck cars. In other words, we try to regulate the headway of the double-truck cars to meet the general conditions during the larger portion of the day, and during the rush hours of the morning and evening, particularly in the evening, we either shorten the headway one-half or throw in intermediate cars, but still maintaining the regular headway of the regular equipment of the line; so that, so far as the city of Milwaukee is concerned, we are very strongly impressed with the very great advantages of the double-truck car, many of which have been referred to indirectly in Mr. McCulloch's able presentation of the case; and we experience other advantages, which are governed by local conditions, and would not apply, possibly, in all cities even of the same population.

A question was asked as to the four motor equipment. I might say that during the present year we have had ten interurban cars constructed, running between Milwaukee and Waukesha Beach and the city of Waukesha, a distance of 26 miles, or slightly in excess. These cars were carefully constructed after complete investigation and the possession of all information we could get from electrical engineers; and based on this and our own experience and judgment, we have equipped them with four 1,000 motors, geared to make 26 miles per hour, weighted with 40,000 pounds. Our double-truck cars are possibly the heaviest in use anywhere in the United States. They weigh about 35,000 pounds. With these four motor equipments we have no trouble from lack of traction whatever, and we are beginning to believe that in the very near future it will be advantageous for us to equip all the double cars with four motors. We have some grades we are climbing with our double truck cars, 33-inch wheels, running up as high as 6 and 7 per cent. They do it with a little difficulty at certain times—certain conditions of rail and weather—but with our four motor equipments we usually have no difficulty whatever in climbing the grades, and in getting, we believe, very superior service.

I think, Mr. Chairman, that the case of the plaintiff, which Mr. McCulloch has been pleased to term the double-truck car, was so ably presented in his paper that it does not need any other advocate for it, but I should rather have denominated the double-truck car the defendant, because there have been so many attacks made upon it. I can only say, so far as we in the city of Milwaukee are concerned, that the double-truck car has come to stay. The character of the population you are serving has much to do with the discrimination that is shown in the selection of a car to ride in. Some sections of the city do not pay much attention to it, and there are other sections that discriminate, and just as you please the pleasure and comfort of the riders we find the traffic increases on those lines. We have what we might call a mechanic district in our city which uses our Third street line, which was equipped during the present year, and there is a marked increase on that line. I might say, as indicating the economy of the double truck, that on certain lines equipped two years ago with double-truck cars we had previously maintained a headway of four and a-half minutes, and by the use of the double-truck car, and the greater speed obtained, together with the greater number of passengers accommodated on this line, running through the better portions of the city, we have been able to gradually lengthen out the headway to six minutes without any complaint from our patrons. You can readily understand what that means in reduced equipment. Quite recently, within the last three months, by a further increase in the speed, on a long line—our policy is to run long lines from one extreme of the city to the other, for the comfort of the passengers and to avoid transfers—we have recently cut off another car and still maintain the headway at six minutes by increasing the speed and making the trip in 90 minutes instead of 96 minutes. I might say that in the same way on the Third street line, the line last equipped, we hope by the increased speed that we will be able to maintain by the use of these double-truck cars over the oscillating single-truck cars, we will be able to take off two of the 16 cars on the line and reduce the number to 14. This is one of the very great economies which we are realizing throughout the system by the use of these double-truck cars. We are able to run at very high speeds on our line from Milwaukee to Waukesha with the double-truck cars, whereas with a single-truck car it would be hazardous to run the car at such speeds, and they could not be kept on the track. The experience of the city of Milwaukee is strongly in favor of the double-truck car. The latest improved truck permits us to use the 33-inch wheel with the same facility as the 30-inch wheel, no greater height from the rail; and I think as soon as our necessities are known the manufacturers of trucks and cars will accommodate themselves to the new conditions and many obstacles will be overcome.

Mr. Bean (St. Joseph)—I move that the report be received and spread upon the minutes and a vote of thanks extended to Mr. McCulloch for his able paper.

Carried.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING PLANTS.

Albion, N. Y.—The property of the Albion Electric Company has been formally transferred to the new electric light company, whose capital stock is $50,000. J. H. Rollins, superintendent of the old company, will serve the new one in the same position. The old plant is to be used until the 400 horse-power plant at Waterport is installed.

Erie, Pa.—Application has been made for a charter by the Erie County Electric Company which proposes to produce electricity for heat, light and power. The incorporators of the company are William C. Readio, William E. Brown, William S. Carroll, William G. Reed and Fred Einfeldt.

Geneva, Switzerland.—The great electric works in this city which supplied light and motive power to the whole canton were destroyed by fire on the night of the 7th inst.

Henrietta, Tex.—E. B. Carver is reported to be interested in a company which is to be organized, with a capital stock of $6,000, for the erection of an electric light plant.

Kokomo, Ind.—Charles Willitts of this city has been appointed receiver of the Citizens' Light & Power Company. The company is capitalized at $75,000. It had a contract for street lighting at $70 per lamp.

Little Falls, Minn.—The city council has ordered a special election for October 4 to enable the people to vote on the question of issuing $60,000 of bonds to purchase the present waterworks and electric light plants, or construct a new plant if the corporation owning the plants refuse to sell.

Montpelier, Vt.—The stockholders of the Consolidated Lighting Company have voted to ratify the action of the directors regarding the acquirement and purchase of the Bolton water power. A resolution was also passed, retiring and cancelling all the preferred stock in the treasury, some 1,250 shares, and to increase the capital stock of the company to $91,349 by issuing 2,784 shares of common stock at $10 each.

Thibodaux, La.—An ordinance will be submitted to the voters of this town at the November election providing for the establishment of an electric light plant.

Wayne, Neb.—The city council has awarded the contract for putting in a complete electric light plant to the John R. Burke Electric Supply Company of Omaha. The plant is to be completed and in perfect running order in ninety days.

Westerville, O.—The city council has passed an ordinance granting a ten-year franchise to the firm of Bennett & Arick, who constitute the Westerville Electric Light Company. A contract for electrically lighting the city for five years will be given the company.

West Superior, Wis.—The council has decided to award the city lighting contract to the Superior Water, Light & Power Company, the company having agreed to furnish lights at the same price that Mr. Burgess did in his proposition, which the council had already accepted. The basis for the contract is $80 per light of 2,000 candle power.

Winona, Miss.—The Blackston Mercantile Company may be addressed concerning the establishment of an electric light plant.

Wichita, Kan.—There is not now an electric light burning in the streets of Wichita at night. The light company notified the city officials that on September 1 the rate would be increased from $6 per arc light per month to $7. The council ordered all lights off the streets and steps are being taken to get a new plant. [After the above was in type we learned that the company had agreed to furnish lights at the old price.—ED.]

STREET RAILWAYS.

Albany, N. Y.—A certificate of consolidation of the Buffalo, Tonawanda & Niagara Railroad Company and the Tonawanda Electric Railroad Company has been filed with the Secretary of State. The consolidated roads will be known as the Buffalo, Tonawanda & Niagara Falls Electric Railroad Company. The capital stock of the new corporation is $1,500,000, and its directors are Henry B. Smith and H. M. Gillett of Bay City, Mich.; T. E. Ellsworth of Lockport; George Sandrock, James A. Roberts and C. M. Howard of Buffalo; James Low of Niagara Falls, and J. A. Read and B. S. Rand of North Tonawanda, N. Y.

Bennington, Vt.—The Bennington & Woodford Electric Railroad was closed to passenger traffic for the season on the 6th. The road, which runs up among the mountains nine miles northeast of Bennington, is used only for summer business. The road has had a successful season.

Chippewa Falls, Wis.—Eau Claire and Chippewa Falls are now connected by an electric street railway. The line was opened on the 2d inst. It is owned by the Chippewa Falls Railroad Company.

Cohoes, N. Y.—The worst disaster in the history of trolley roads occurred in this city on the night of the 5th inst. An express train of the Delaware & Hudson Railroad Company dashed at almost full speed into a car of the Troy City Railway Company which was full of passengers, totally demolishing the car, killing eighteen persons outright and fatally wounding ten others, several of whom have since died. Among the seriously injured was the motorman of the trolley car.

Detroit, Mich.—The Detroit, Lake Shore & Mt. Clemens Electric Railway Company celebrated the opening of their road on the 1st inst. by an excursion over the line and a "sumptuous supper" at McSweeney's. The cars of the company are described as things of beauty, the woodwork being of a rich selection of Cuban birch, and the reversible seats handsomely upholstered in old gold plush. Several innovations in suburban cars are introduced, such as smoking apartments and drawing rooms for private parties, which latter are equipped with individual leather upholstered chairs. All the latest improved appliances in connection with the motive power are introduced. The carbon-electric headlight is the most powerful known, throwing a searching ray for several blocks. W. J. Hart is general superintendent of the road.

La Crosse, Wis.—A new company, to be named the La Crosse & Black River Valley Electric Railway Company, is to be organized and have its headquarters in this city. The proposed route for the road will take it through the villages of Grand Crossing, Onalaska, Holmen, Stevenstown, Burr Oak, East Melrose, Putnam's, Pine Hill and Black River Falls. The line would be over 46 miles in length.

Mobile, Ala.—The two street railroad companies of Mobile employ 300 white men whose average pay is $1 60 per day. Both companies have complete shops for the repair and manufacture of cars. During the past year the Mobile Street Railroad Company has constructed a number of very handsome trolley cars. The annual pay roll of this company amounts to $50,000.

New Brunswick, N. J.—A report has reached here that the Brunswick Traction Company has assumed full control of the trolley line from Bound Brook to

Raritan, the transfer by the New York & Philadelphia Traction Company having been completed. The Brunswick Traction Company will operate the line.

Needham, Mass.—A corporation, to be known as the Needham & Boston Street Railway Company, is being formed here for the purpose of constructing and operating a street railway between Needham and West Roxbury.

New York.—The Broadway cable lines are to be changed at once to the underground trolley system. Work has already begun on the conduits on lower Broadway.—It is stated that the Union Railway Company has contracted to purchase the Yonkers Electric Railway, and beginning this week passengers will be carried from any part of Mt. Vernon to any part of Yonkers for a single fare of five cents. As soon as permission is granted to lay tracks across the Harlem Railroad and the line in New Rochelle is completed, through cars will be run from Yonkers to New Rochelle for a single fare of five cents.

Oakland, Cal.—The city council has granted the Oakland Railroad Company permission to use electricity upon its San Pablo avenue line.

Rockford, Ill.—The City Railway Company and the Rockford Traction Company, which were to be consolidated in case a 25-year extension of franchise could be secured, have refused to accept the franchise offered them by the council, claiming that burdens were imposed which, if accepted, would make it impossible for the consolidated company to do business and live.

Wheeling, W. Va.—The Wheeling Railway and the Bellaire, Bridgeport & Martin's Ferry Railway companies have been consolidated and both systems will be under entire control of the Wheeling Railway Company which has also an option on the Moundsville & Wheeling road.

MANUFACTURING, ETC.

Boston.—The "News Bureau" of the 9th inst. says: "We understand that the Walker Company is running its works to the fullest capacity and that in view of the fact that its capital of $2,500,000 is not sufficient to care for the large business it is doing, its capital stock will soon be increased to an amount not yet decided upon. Such new stock will be taken by the directors of the company, which include R. P. Flower, A. N. Brady, J. W. Hinckley, Perry Belmont and others equally well known. The company is at present a close corporation, and it is the intention to keep it so for some time to come."

Brooklyn, N. Y.—The Willard third-rail system of electric traction is to be installed upon a two-mile section of the Long Island Railroad during the latter part of the present month, to give a practical demonstration of the effectiveness and safety of this system.

Cleveland, O.—The Walker Manufacturing Company has, it is stated, signed a $300,000 contract with the Brooklyn Heights Railroad Company of Brooklyn, N. Y. The Walker Company will make for it 600 motors and electrical equipments. The company is expected to deliver them within six months.

TRANSMISSION PLANTS.

Niagara Falls.—The fifth 5,000 horse power dynamo in the Buffalo avenue power house of the Niagara Falls Power Company was tested a few days ago and found to be in perfect condition. The great machine moved without a hitch of any kind.

PROPOSALS.

New York.—Proposals are invited for engines, generators, the electric wiring and fixtures, etc., for the new hospital buildings of the Manhattan State Hospital at Central Islip, the proposals to be delivered in person or sent by mail up to 4:30 P. M. September 22 to Hon. Henry E. Howland, president of the board of managers, No. 1 Madison avenue, New York City. At that number drawings and specifications may be consulted and blank forms of proposals obtained.

PERSONAL AND MISCELLANEA.

The New Orleans papers at hand report the resignation of Superintendent James B. Craven of the Edison Electric Light Company of that city.

Philip Gabler, electrician of the Bleecker Street Railroad, Utica, N. Y., succeeds Frank L. Everts as superintendent of the road, the latter having resigned.

Galen C. Moses of Bath, Me., has assigned for the benefit of his creditors to Symonds, Snow & Cook of Portland, the assignment covering property valued at $400,000. Mr. Moses has been interested in electric railroad building and has been regarded as one of the wealthiest men in Maine.

A feature of the exhibits at the Street Railway Convention at Boston that attracted much attention was a gigantic globe and map of the world, 24 feet in diameter, placed in the center of the lower hall, and towering up through the light shaft into the upper hall. This geographical enterprise was not so much for displaying new political possessions as for impressing the observer with the extensive field of a large electrical firm which builds street railroads in various places that were indicated on the map in the evening by small electric lights. The demonstrator pointed out with special pride an isolated spot in the south of Africa. A miniature electric railroad formed the equator of this globe.

Thomas Farrell, assistant engineer at the works of the Lockport Gas & Electric Light Company, Lockport, N. Y., was killed by an electric shock on the night of the 31st ult. He was noticed leaning heavily against a dynamo by one of the workmen, who went up to see what was the matter and took hold of him to pull him back. As he did so Farrell fell to the floor in a heap; life was extinct. It is supposed that he accidentally touched both poles of the machine, making a circuit which passed nearly 2,000 volts of electricity through his body, causing instantaneous death.

INCORPORATIONS.

The Universal Electric Company, Portland, Me.—Capital stock, $150,000.

The Peninsula Electric Light & Power Company of Houghton, Mich., has increased its capital from $150,000 to $200,000.

The Mill Creek Valley Street Railroad Company of Cincinnati, O., has increased its capital from $500,000 to $1,750,000.

The Westerville Electric Company, Westerville, O. Capital stock, $9,000. Incorporators: C. L. Bennett, R. B. Adams, H. E. Chinn, E. S. Aldrich, O. W. Aldrich.

The Buffalo Manufacturing Company, Buffalo, Wyo.—to manufacture flour and put up electric light works in Buffalo, Wyo. Incorporators: C. J. Hogerson, W. J. Thorn and E. D. Metcalf.

The Mitchell Electric Company, Portland, Me.—to manufacture and deal in electrical appliances. Capital stock, $150,000, of which $2 is paid in. President, Thomas H. McDonnell of Quincy; treasurer, William E. Pearson of Boston, Mass.

The Minneapolis & Champlin Suburban Railway Company, Minneapolis, Minn. Capital stock, $150,000. Incorporators: Emery W. Hill, Lorenzo L. C. Brooks, Collinwood Evans, Henry M. Norton, Fremont S. Woodbury, Clifford S. Staples and Anthony Chryst.

Articles of incorporation of the American Indies Company, with $18,000,000 capital, were filed with the Secretary of State of New Jersey at Trenton, N. J., on the 6th inst. The incorporators are Thomas Dolan, P. A. B. Widener and W. L. Elkins of Philadelphia; Thomas F. Ryan, Frederick P. Olcott, A. N. Brady, R. A. C. Smith, Henry D. Macdona, J. N. Ceballos, Guillermo de Zaldo, H. P. Booth and H. G. Runkle of New York. The company has a general charter authorizing it to build and operate electric plants, telegraph, telephone, steamship and railway lines, to conduct real estate and mining operations and to carry on business in a number of other branches.

ELECTRICAL PATENT RECORD.

Letters Patent Issued September 6, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

610,241. Collector for Electric Railroads. Fred S. Pearson, Boston, Mass. Filed March 31, 1897.
610,445. Electric Railroad. John C. Henry, Denver, Col. Filed June 30, 1898.
610,238. Car-Fender. Harry Lehrer, New York City. Filed May 20, 1898.

ELECTRICAL MACHINERY AND APPARATUS.

610,350. Means for Supplying Electric Currents to Agricultural Machines. Hugo Foerster, Gorsdorf, Germany. Filed Jan. 8, 1896.
610,402. Electric Switch. Rudolf L. L. Hundhausen, Wilmersdorf, Germany, assignor to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed Dec. 31, 1897.
610,406. Resistance and Contact Apparatus for Electric Currents. Henry Lyon, Glasgow, Scotland, assignor of one-half to the D. Stewart & Co., Limited, same place. Filed July 6, 1898.
610,413. Direct-Current Regulator. Frederick E. Ramsay, Walsenburg, Col. Filed Jan. 28, 1898.
610,509. Means for Controlling Voltage and Volume of Electrical Currents. Harry Williams, Cleveland, O., assignor to the Morrison Battery Company, same place. Filed Dec. 8, 1897.

ELECTRIC ELEVATORS.

610,197. Controlling Device for Electric Elevators. Norton P. Otis and Rudolph Smith, Yonkers, N. Y., assignors to the Otis Brothers & Company, New York City. Filed April 4, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

610,274. Telautograph. Leon O. McPherson, Highland Park, Ill., assignor to the Gray European Telautograph Company, Chicago, Ill. Filed March 13, 1897.
610,278. Telegram-Transmitter. Edward Porter, Sydney, New South Wales. Filed Sept. 4, 1897.
610,339. Telegraph-Tape. Frank Atherton, Paterson, N. J. Filed Nov. 12, 1897.
610,347. Telephone. William A. Drysdale, Philadelphia, Pa. Filed Sept. 17, 1897.
610,393. Telephone. Sydney S. Fisher, San Francisco, Cal. Filed Jan. 14, 1897.

MISCELLANEOUS.

610,190. Secondary Battery. George J. Miller, Kenton, O. Filed April 13, 1897.
610,214. Dental Engine. John D. Wilkens, Chicago, Ill., assignor to John N. Crouse, same place. Filed Oct. 11, 1895.
610,229. Electric Clock Train. Charles M. Crook, Elgin, Ill., assignor to Charles S. Burton, trustee, Oak Park, Ill. Filed April 29, 1897.
610,465. Explosive-Engine. Alexander Winton, Cleveland, O. Filed Sept. 18, 1897.
610,511. Miner's Safety-Lamp. William Best, Morley, England, assignor to the Ackroyd & Best, Limited, same place. Filed Dec. 23, 1897.

TELEPHONE AND TELEGRAPH.

Old Time Telegraphers' Meeting.

The greatest gathering of telegraphers since the civil war is now holding sessions at Omaha, Neb., as the meeting was set for three days beginning on the 13th and ending on the 15th inst. It is the annual meeting of the Old Time Telegraphers' Association and the United States Military Telegraph Corps, and the attendance is not confined to membership in the organizations named, but is augmented by hundreds of outside telegraphers. An Omaha dispatch states that a leading feature to be witnessed is the ascension of the great war balloons with telegraph and telephone attachments that were used at Santiago. At the Trans-Mississippi Exposition an Indian war dance has been specially arranged for the telegraphers, as a reminder of exciting experiences to operators who saw frontier service. Besides the Exposition attractions proper, the telegraphers will be treated to a grand concert by the Mexican National Band, an exploration of the Midway under the leadership of the president of the Old Time Telegraphers' Association, a reception at George W. Leininger's art gallery, one of the finest collections in America, visits to the packing houses, and a farewell banquet overlooking the grand court of the Exposition.

At the Merchants & Manufacturers' Board of Trade regular monthly meeting in New York on the evening of the 7th inst., R. M. Walters, chairman of the Committee on Telephone Legislation, urged that an aggressive campaign be made this fall in the interest of lower telephone rates in New York City, and the committee was asked to make a full report at the next meeting. Five members of the board were made a committee to prepare an address to be sent to the Republican and Democratic State Conventions requesting that a measure for lower telephone charges be incorporated in their platforms. The committee consists of R. M. Walters, Charles Heckman, E. R. Lyon, Francis O'Neill and E. J. Gavegen.

The E. H. Martin Telephone Company has completed a new copper circuit wire connecting Webster City with Marshalltown, Ia., and expects to reach Gowrie in a day or two. This company's exchange in Webster City was established only a few years ago by a young man of limited means, now it has 500 miles of wire and forty local stations outside of Webster City and 200 'phones in use in that city.

The Dakota Central Telephone Company has had a representative at Pierre, S.D., making arrangements to extend its line west from Wolsey. The system with its connections extends to all cities in the eastern portion of the State, and its connection with the line from Pierre to Rapid City will insure a telephone system for the whole State.

Chas. Boyce, for several years superintendent of equipment of the Michigan Bell Telephone Company, has accepted the management of the Citizens' Telephone Company of Grand Rapids. He is considered one of the most expert telephone men in the country and has invented several improvements and attachments.

The San Diego, Cal., *Sun* states that within three weeks the Sunset Telephone Company will have its line completed into Portland, Ore., a distance of 1,500 miles from San Diego, and this will make it the longest telephone line in the world.

The Mississippi Valley Telephone Company is pushing the laying of conduits in St. Paul, and the pole line to Minneapolis is being rapidly constructed.

The Lawrence Telephone Company has been organized at Iron City, Tenn., to construct a telephone system.

J. T. Alexander is about to establish a telephone exchange in Providence, Ky.

New Companies Incorporated.

The Citizens' Telephone Company, Edinburg, Ind. Capital stock, $1,500.

The Home Telephone Company, Woodruff, S. C. President, E. F. Pearson; secretary, L. H. Irby; treasurer, S. J. Workman.

The Silver Creek Telephone Company, Yazoo City, Miss. Capital stock, $1,000. Incorporators: R. M. Beaman, Smith & McDonnell, T. W. Fisher and others.

The Missouri & Illinois Telephone Company, Meyer, Ill.—to conduct a telephone business. Capital stock, $2,500. Incorporators: O. C. Clay, W. B. Henton, H. C. Chinn.

The Huntingdon County Telephone Company, which proposes to operate and maintain a telephone system in the counties of Huntingdon, Bedford, Blair, Centre, Fulton, Mifflin, Juniata and Perry, Pa., and to connect with other lines, was chartered at Harrisburg on the 2d inst. The system to be used is a new one. The capital stock is $2,500.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12⅛c.; Lake, 12½c.; casting, 11⅞@12c.

The American Railway Electric Light Company announces an increase of capital stock from $2,500,000 to $3,000,000.

The United Traction & Electric Company of Jersey City has declared a dividend of ¾ per cent., payable October 1. Transfer books close September 21 and reopen October 4.

The annual report of the Metropolitan Street Railway Company, New York shows gross earnings of $9,938,503; net earnings, $4,638,069; surplus after charges, $1,845,570.

The Commercial Cable Company has declared its regular quarterly dividend of 1¾ per cent., payable October 1. Books close September 20 and will reopen October 3.

Application has been made to the New York Stock Exchange to list the reduced capital stock of the General Electric Company, $18,276,000 common stock and $2-551,200 preferred.

It is announced from Chicago as practically certain that the South Side "L" directors will be able to declare a lump dividend of 3 per cent. for 1898 if they are so disposed, the only question being if this year's earnings will not be put into extensions or new equipment, instead of being paid out to stockholders.

The Glens Falls, Sandy Hill & Fort Edward Street Railroad Company has filed its annual report with the New York Railroad Commissioners. The gross earnings for the year were $61,537; operating expenses, $44,556; other income, $2,882; fixed charges, $11,082; net income, $8,781; dividends, $7,225; surplus, $1,556; total surplus, $8,184.

President Coffin of the General Electric Company notified stockholders of the company by circular last week that the new certificates represented by the reduced number of shares would be ready for issuance on September 12, on which date transfer books would be opened. Convertible certificates will be issued for fractional amounts.

The stockholders of the American Telephone & Telegraph Company, at their special meeting on the 8th inst., voted to increase its capital stock from $20,000,000 to $25,000,000. A Boston financial paper states that the American Bell Telephone Company, which owns practically all the stock of the American Telephone & Telegraph Company, will take the additional stock the stockholders of the latter company have just authorized to be issued.

At the annual meeting of the United Electric Securities Company, Boston, held in Portland, Me., on the 8th inst., Philip Dexter and N. W. Rice were added to the board to succeed Arthur Perry and W. H. Whitney. A majority of the preferred stock was represented, the common stock being represented in full. The company invites proposals for sale to it of so many of its collateral trust 5 per cent. bonds of the fifth, eighth and ninth series as can be purchased with $59,421. Sealed proposals will be received until 12 M. September 21.

The Chicago "Record" of the 7th inst. says: "It is rumored that the Central Union Telegraph Company is about to resume dividends on its $6,605,300 capital stock. The company paid a dividend of 1 per cent. in 1896, but nothing in 1897. The affairs of the concern are said to be in a prosperous condition, and an increase in the earnings for the fiscal year is expected to the amount of about $500,000. The company operates the Bell Telephone Company's instruments in Indiana, Ohio and Illinois, except in Cook County. The earnings of last year were $1,436,898 gross. Operating expenses, which have been very heavy—about 81 per cent.—will be reduced."

The Louisville, Ky., "Courier-Journal" of the 8th inst. has the following: "Messrs. John C. Russell, St. John Boyle and George C. Norton will leave to-morrow for New York to attend a meeting to reorganize the New Orleans Traction Company. The gentlemen from Louisville will be met in New York by Mr. R. M. Walmsley, George Denegre, Albert Baldwin, C. H. Hymes and Mr. Howard of New Orleans, and a representative of Clark & Co. of Philadelphia. The meeting will be held September 15. The Louisville committee will have a plan of reorganization which will be submitted to the other gentlemen. There are some points of difference which the meeting is expected to decide."

A deed has been filed in the office of the Recorder of Deeds, Washington, D. C., which transfers the entire property of the Washington & Maryland Railway Company to the new City & Suburban Railway Company, formerly the Eckington & Soldiers' Home Railway Company. The consideration named is 10,000 shares of the capital stock of the City & Suburban Company of the par value of $500,000, and 200 of its first mortgage bonds, aggregating in all $700,000. In pursuance of the sale the Washington & Maryland Company delivers over all of its bonds for cancellation. The value of the real estate transferred is given as $240,000, and upon this amount the internal revenue tax was paid.

Henry A. Everett, of Cleveland, O., said in an interview a few days ago concerning the recent advance in Big Consolidated stock: "We have brought the stock up to where it belongs, that is all. The stock has not been quoted for what it is worth, and it is singular how ready the people are to sell when the stock is quoted at something like its real value." "Why has it been too low?" was asked. "There are several reasons. I will name one. Mr. Tom L. Johnson has been getting rid of a large quantity of the stock. He has unloaded something like 17,000 shares of it. Of course that would have a depressing effect on the market quotation."

A New York correspondent of the Boston "News Bureau" writes as follows: "We understand that the recent advance in General Electric has been brought about by a bull pool including several local operators. They thought conditions were right for a speculative turn intended to carry the price from 37 to the neighborhood of 50. The advance has not had support of insiders very fully. Insiders regard General Electric as worth only about the present price even if the company pays 6 per cent. on the new stock. It is quite possible that the price will go higher, but there will probably be a fair amount of realizing from this point up."

ELECTRICITY.

Vol. XV. NEW YORK, SEPTEMBER 21, 1898. No. 11.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4081 Cortlandt.

EDITORIAL NOTES.

A New "Combine." The consolidation of the Westinghouse Electric & Manufacturing Company with the Walker Manufacturing Company was announced a few days ago. This new development in the electrical field may come as a surprise to some, but not so to us, as we have all along known that some such combination would sooner or later take place. The consolidation deal is said to have been under consideration for some time, but was only consummated on the 16th inst. Ostensibly the consolidation was the result of recent patent litigation, and was brought about, so it was claimed, principally with a view to reducing this item of expense, which is said to have consumed profits. It is unquestionably true that immense sums of money have been spent in litigation over trolley patents, and that recently, but we question whether this fact had any great weight in bringing about the present condition of affairs. In our opinion a number of wealthy financiers got interested in the Walker Manufacturing Company a short time ago without being fully acquainted with the exact condition of the electrical industry. As a result these gentlemen were obliged to accept the securities of the company which they had originally proposed to sell to the public. Every endeavor was then made by the new owners to secure as large an amount of business as possible, which they succeeded in doing, but unfortunately for those interested, the prevailing prices for electrical machinery were so low and there was so much competition that, in spite of the fact that the shops were full of work, little or no profit was being derived. A consolidation with the Westinghouse Company was apparently the easiest way out of the dilemma, and this appears to have been effected without any pecuniary consideration on either side, a block of the Westinghouse stock and bonds being exchanged for Walker securities upon a given ratio. By this arrangement competition in the line of street railway apparatus will be reduced as well as operating expenses. Again as of old, the employes will be the sufferers, as in all other consolidations.

* * *

Horseless Carriages. It would seem as though the Automobile Exposition recently held in Paris had caused many adherers of the mineral spirit motor driven carriage to somewhat change their views and acknowledge that for cleanliness, comfort and simplicity of operation the electrically propelled vehicle surpassed that driven by any other form of motive power. In the study of this problem of automobilism France is apparently far in the lead of any other country, as prizes have repeatedly been offered for road races and other suitable tests between vehicles propelled by electricity and various forms of steam and spirit motors. The late Exposition, as was to be expected, brought out a large array of almost every type of automobile. In one form of vehicle exhibited, the front wheels by which the carriage is propelled are separately connected each to its own motor. The latter are not securely fastened so as to remain at all times stationary but turn with the axle in steering. The motion is transmitted from the motors to the wheels by a simple arrangement of gears. It is claimed for this system that the vehicle may be turned in a very narrow space and that no complicated system of gearing is required to effect this. The storage batteries are, as is customary, located under the seats, the whole vehicle weighing about 2,500 lbs. Such an automobile can travel, so it is claimed, a distance of 44 miles without the batteries having to be recharged, at a speed varying between four and one-half and thirteen miles an hour.

In another form of automobile exhibited the motor is attached to the rear wheels, the armature having a double winding. With a view to reducing the weight to a minimum, the inventor of this system has had the motor casing and other such parts made of aluminum. The weight of the storage batteries for a five-seated phaeton of this description is 925 lbs. and for a two-seated vehicle 550 lbs. It is claimed that the batteries employed in this case will develop one horse-power for every 42 lbs. of weight, but whether this is so would seem problematical.

Although this country has by no means taken the interest in the horseless carriage problem that France has, there are at the present time in actual operation in New York City alone over one hundred automobiles. These are mostly in the form of hansoms and may be hired by the general public, having been built for this purpose by a company. These conveyances are propelled by means of a motor attached to the front wheels which can be made to exert a propelling force of from two to four horse-power. The requisite current is stored in 48 storage cells of 100 ampere hours' output. The storage batteries for each vehicle weigh about 1,250 lbs., each cell being incased in a rubber jar. The total weight of a hansom of this description, which is now fast becoming a common sight on the thoroughfares of this city, is 3,000 pounds. The feature of these hansoms which probably strikes the observer the most on first sight is the peculiar construction of the wheels. These instead of being built with wooden or metal spokes as in the case of the French automobiles are made of two metal plates ⅛ inch thick. This form of construction, although materially strengthening the wheels, and thus making them more durable, gives one the impression of weight and makes the carriage look clumsy. In fact, as may be seen from

the above figures, the hansom automobile as at present in use in this city weighs some 500 lbs. more than a French conveyance capable of carrying one or two more persons. In this case as in many others in this country, we have sacrificed beauty of design for strength. That the automobile, whether electrically propelled or otherwise, will never become popular in the United States, as it appears to be gaining in France, for country use and long distance runs, is an assured fact, for in traveling from one point to another the average American would prefer the more speedy and commodious means afforded by the railway. For city work, however, the electric automobile would seem to have advantages which should bring it more and more into practical use as the weight of storage batteries for a given output is reduced.

* * *

The Telephone Situation in London.

To the average American some of the facts brought out by the report recently issued by a special committee of the English Parliament on a method of improving the telephone service in London are surprising to say the least. That the largest and presumably one of the most enlightened cities in the world should be so tardy in adopting telephone facilities is astonishing. From all accounts many cities of one-tenth the population of the great English metropolis have as many or more call telephone offices and consequently better service.

A few years ago the telephone service in the United Kingdom was in the hands of the Government, as the telegraph service now is, both being run as a department of the Post Office; subsequently, however, it was thought advisable to grant a license to a private corporation, known as the National Telephone Company, to operate local exchanges, which license expires in 1911. The principal reason why the telephone has not become more popular in London would, however, seem to be, not the poor quality of service furnished, but the spirit of conservatism which prevails in England and to which may be attributed the fact that that country even now possesses but a few hundred miles of electrically propelled street railways. The following extract from the London correspondent of the New York *Sun* gives an excellent idea of this senseless conservatism :

"One of the principal banking houses of London installed a telephone in its chief office a few months ago. It proved a great nuisance. They were constantly called up about business matters which were usually dealt with by messenger. The clerk whose duty it was to answer the calls complained to the directors that his other work was much interfered with by the telephone bell. So the directors considerately ordered the removal of the offending instrument. Less than a week later the bank was mulcted in £1,200 by a clever swindler with a fraudulent check. Another banker had tried to send advance warning of the fraud by telephone, and the messenger whom he sent subsequently arrived too late. But even this lesson did not procure the reinstallation of the telephone. As a matter of fact, it is not considered quite respectable for a conservative banking house in London to include this new-fangled contrivance in its equipment."

As previously stated, the main object of the special committee of Parliament is to discover the defects of the present system with a view to its betterment. In the opinion of this committee the service as it now exists is inaccessible to those who only desire to use the telephone occasionally. To reap the full advantage it is necessary to pay a comparatively heavy subscription in return for a privilege quite limited in extent. The present system gives access to telephones only to subscribers, regarding which the special committee says :

"Just as if the Post Office should decide to despatch telegrams only from persons paying an annual subscription, and to allow such persons, on payment of their subscription, to despatch, without further charge, any number of telegrams, requiring at the same time that telegrams should be addressed only to persons connected with the Post Office telegraphs by private wires."

The Swiss plan is strongly advocated by the committee for the following reasons :

"Messages can be sent by non-subscribers from call offices and delivered to non-subscribers by express messengers, but, in addition to this, just as some persons in this country hire private telegraph wires to connect them with the general telegraph service, and thus avoid the necessity of delivering messages at or receiving them from a telegraph office, so persons who wish to save the journey to a call office to despatch a telephone message or to receive it direct instead of by a written message, can secure a private telephone in their house or office on payment of (after two years) £1 12s. For all messages actually sent subscribers and the public alike pay the same fixed toll, smaller if the message is a local one, larger if it travels over the trunk wire; the price for all distances over trunk wires in Switzerland being the same. Each message sent by a subscriber is numbered and an account against him is kept. It follows under this system that every telephone can be used by the general public instead of being confined to the actual subscriber, with the result that in many towns every shop or place of business which has a telephone becomes in practice a public call office."

One hundred dollars a year for so-called unlimited service in London does not at first sight seem exorbitant, but when it is recalled that probably one-half of the business transacted by telephone in this country has to be carried on by means of private messengers, on the other side, owing to the scarcity of telephone connections, the rate charged would seem ample.

Under the Searchlight.

Notes and Comments on Various Topics.

It is somewhat mortifying to have to acknowledge a delinquency, but when one is unfortunate it is just as well to be humble and confess. Owing to unavoidable circumstances and an unreliable reporter, we failed to give an account last week of an affair which was well worthy of prompt record. We refer to the electrical clam dinner given at the Pomham Club, Providence, by Mr. Eugene F. Phillips and the American Electrical Works. We had secured the services of an expert note-taker of high gastronomic intelligence and a keen appetite for everything choice in the fish line, so he claimed, and rested easy in the expectation of getting a report of the proceedings at that dinner that would insure the sale of at least a thousand extra copies of the paper and be read with avidity by every clam baker in the country and along shore. His report failed to reach us in time for last week's paper ,and when the man himself put in his tardy appearance he offered the apology that the clam dinner was such a fine affair and so prismatic in its multitudinous enjoyments that it would be damaging for any serious reporter's reputation to attempt a hasty description of it, so he had jotted down a few of the best-balanced occurrences and set out for the train that he expected to take for home. When he reached the depot he found that he had a couple of hours to wait, so he thought he would take a run round the State and see the landscape. The walk was longer than he had estimated, for there is a good deal of land in Little Rhody after all, and when he returned to the depot the train had departed. This rattled him, and, as was to be expected, having failed to accomplish what he was employed to do, he decided to let the world go by and put his trust in Providence. When we tackled him for his neglect, he bore our censures without even a blush, sustained apparently by the recollection that anyway he had enjoyed a royal feast of clams and the company of a big crowd of the brightest fellows in the electrical business, and had seen much of the territory that Roger Williams and Anne Hutchinson had chosen as an asylum from Puritan fanaticism.

The clam dinner, as is now well known, came off at the time set, on the 10th inst., and was voted superb by all who attended it, and these had gathered from all sections of the country not included in our new territories. At the next annual clambake of the American Electrical Works, we have no doubt that the veteran host, Mr. Eugene F. Phillips, will have the satisfaction of greeting several new faces, some perhaps of Mongolian contour, from the lands our conquering squadrons and armies have added to our possessions. We trust our reportorial arrangements at that time will be adequate to the occasion, and carried out without necessitating a gall-shriveling apology.

* * *

In order to meet the difficulties experienced with railway car brakes, the ingenious Kubierschky brake, says the *Scientific Press*, has been invented. It is composed of four steel segments and coils inclosing one of the car axles, the segments being bolted together and acting as a brakeshoe, thus forming a rigid system that is bolted, by means of a projecting shank, to an arm arranged in the under frame of the car. In front of the shoe is an iron disk, fixed and keyed to the car axle, which forms the armature to the shoe, this being held at its proper distance from the shoe by springs. On an electric current being passed through the coils, the friction surface of the brakeshoe is brought into contact with the disk, checking the rotation of the axle and the progress of the car. At Dresden, as reported, the application of the brake to a seven-ton car traveling at fifteen miles an hour brought the car to rest within a distance of forty feet.

A Use for Liquefied Air.

It is reported that a use has been found for liquefied air, the possibilities of which have been matters of discussion among scientific men for some time. According to the *Mining Reporter*, a discovery was made recently by which it is now practicable to use liquefied air in underground work, such as mining, driving tunnels and sinking shafts. It is said that under proper conditions the liberation of air from the liquid can be effective in generating power with which to run drills under ground, pumps, hoists, etc., while cool air can also be supplied in the deepest mines. The liquid air can also be used in freezing soft ground, making tunnel cutting less hazardous and tedious. If there is any reliability in this reported discovery, and its success can be practically demonstrated, it will make a new departure in the lines of work named, and once again make the genius of science the soul of industrial progress.

* * *

The *Electrical Engineer*, London, referring to the General Electric Company, says : "This large manufacturing and financing concern does an enormous business, but has not been able for years past to make money for its shareholders. Hence the conclusion arose that the business was over-capitalized, and by a special resolution the capital has been reduced from £6,092,000 to £4,165,400. There is no doubt that the company originally valued its patent rights too highly, and that the smaller sum more nearly represents the value of the undertaking. Even at this value no figures are published to show that dividends can be paid, but the officers of the company say that this is the case. It is a pity that such large ventures should not be run, at least to some extent, in the interests of those who have found the money to start them."

CANADIAN NOTES.

Mr. J. W. Poupore, M.P. for Pontiac, is negotiating with an American syndicate capitalized at $5,000,000 to erect smelters at Ottawa and Georgian Bay in connection with the Ottawa ship canal. In relation to this, a gentleman is in Ottawa to patent an electrical smelter.

Complaints have been made to the Agricultural Department of Canada by Montreal shippers respecting damage occasioned to perishable articles of export, owing to lack of proper ventilation on some of the steamships. It is understood that at least fifteen of the principal ocean-going steamers sailing out of that port will be fitted this fall with electric apparatus for proper ventilation.

The city council of Toronto, Ont., has accepted the tender of the Sprague Elevator Company of New York for the supply of three electric elevators, with the plant for five, for the new municipal buildings of Toronto. The architect states that the electric plant will operate 300 or 400 lights in addition to the power required for running the elevators.

A company of capitalists in Winnipeg, Manitoba, purposes utilizing a portion of the water power on the Winnipeg river. The scheme involves the establishment of an electric railway from the mouth of the Whitemouth river to points along the Winnipeg river, and also the transmission of electric power to the city of Winnipeg.

The Shawinigan Water & Power Company, which proposes to utilize Shawinigan Falls on the St. Maurice River, in the province of Quebec, seventeen miles from the town of Three Rivers, has decided to install at once a plant capable of developing 100,000 horse-power. The plans have been prepared by T. Pringle & Son of Montreal, assisted as consulting engineer by W. C. Johnson of Niagara Falls, N. Y., and the company is now calling for tenders. It is understood that power will be sold at Three Rivers cheaper than it can be obtained at any other port in the world reached by ocean-going vessels, and also at the falls at a proportionately low figure. A strong company has been formed, with the following directorate: A. F. Gault, Thos. McDougall, Hon. L. J. Forget, P. N. Greenshields, all of Montreal, and John Joyce, H. H. Melville and J. E. Aldred of Boston, Mass. The company is confident that the advantages which it can offer to manufacturers on a large scale are so great that it will mark an era in the industrial development of the province of Quebec.

The Cataract Power Company of Hamilton, Ont., formed its first connection with that city last week, sending in 22,000 volts over the wires from its water-power canal near Thorold, Ont., thus demonstrating its ability to convey electrical power a distance of 40 miles. The plant to do this cost about $500,000. A large driving motor of 40 horse power was used in the test, and 200 incandescent lamps had been arranged in the form of a shield which were illuminated. It is expected the company will supply the Hamilton Electric Light and Power Company with power for its dynamos by October 1.

The Edison Illuminating Companies' Meeting.

The nineteenth annual meeting of the Association of Edison Illuminating Companies was held at Sault Ste. Marie, Mich., on the 12th, 13th and 14th inst. About eighty delegates were present. Papers on various subjects connected with electric lighting and management were read. Among the authors of these were W. S. Barstow of the Brooklyn Edison Company, K. W. Liele of the New York Edison Company, A. E. Leslie and Charles S. Shepard of New York; Oliver Bushnell, Chicago; Caryl D. Haskins, Boston; C. E. Perry, Indianapolis, and W. E. Kingan, Sault Ste. Marie.

A large number of ladies accompanied the delegates, and steamboat excursions and social entertainments made the visitors feel that they were abundantly repaid for their trip to the "Soo."

THE BRITISH ASSOCIATION.

(From our London Correspondent.)

The Bristol meeting of the British Association opened on Wednesday, September 7, with the address of the president, Sir William Crookes. The number of members and associates who had registered their names at Bristol up to Wednesday evening was 2,284, including a number of eminent scientists from foreign countries, some of whom were expressly in attendance for the purpose of taking part in the important conference on "Terrestrial Magnetism and Atmospheric Electricity" which is being presided over by Prof. Rucker. References congratulatory in character were made to the conference in several of the sectional addresses. Prof. W. E. Ayrton, F. R. S., in his address to the Mathematical Section expressed himself as follows:

"The earth is an object of much importance to the terrestrial magnetician, the telegraph electrician and the tramway engineer, but while the first aims at observing its magnetism and the second rejoices in the absence of earth currents which interfere with the sending of messages, the third seems bent on converting our maps of lines of force into maps of lines of tramway. It seems as if electric traction is destined in time to annihilate magnetic observatories near towns, and even to interfere with telegraph and telephone systems. The principle of the survival of the fittest is quoted by some electrical engineers, but can the system of electric traction, which has already destroyed the two most important magnetic observatories in the United States and British North America, be the fittest to survive? Again, do we take such care and spend such sums in tending the weak and nursing the sick because we are convinced that they are the fittest to survive? Let the electrical engineer who is inclined to think slightingly of the deflection of a little magnet compared with the whirl of his 1,000 HP. dynamo go and visit a certain dark storeroom near the entrance hall of the Royal Institution, and while he looks at some little coils there ponder on the blaze of light shed over the whole world from the dimly lighted cupboard in which those dusty coils now lie. Then he may realize that while the earth as a magnet has endured for all time, the earth as a tramway conductor may at no distant date be relegated to the class of temporary makeshifts.

"During the present year the publication of abstracts of foreign papers on physics, begun by the Physical Society in 1895, has been continued jointly with the Institution of Electrical Engineers. *Science Abstracts* was the name selected for this periodical, and its contents include general physics with separate sections for each branch, and general electric engineering with separate sections for each of its more important sub-divisions. Its value is already recognized by the British Association and by the Institution of Civil Engineers, who make liberal contributions towards the expenses of publication. It is hoped that finally the scheme may be supported by the scientific societies of many Anglo-Saxon countries, as the saving of time and trouble that will be effected by such a journal can hardly be overestimated."

The International Conference was opened on the morning of the 8th inst. by an address delivered by the president, Prof. Rucker, in which he referred to the danger, alluded to by Prof. Ayrton, of the rapid extension of electrical railways affecting magnetic observatories and thus interfering with researches of ultimate benefit to the whole human race.

A paper was read by Professors E. B. Rosa and W. O. Attwater on "Conservation of Energy in the Human Body." A discussion followed and Prof. Aryton drew attention to the fact that the energy of muscular action is probably capillary or electrical, the human machine being more analagous to an electric battery and motor than to a steam engine. Mr. W. N. Shaw agreed with Prof. Ayrton's view of the electro-chemical nature of the energy of the human body.

A report submitted by the "Committee on Comparing and Reducing Magnetic Observations" was taken as read.

COST OF ELECTRIC POWER FOR STREET RAILWAYS AT THE SWITCHBOARD STEAM AND WATER POWER.*

BY R. W. CONANT.

It is my privilege to be able to communicate to you facts and figures bearing on the operation of forty-four power stations located at the important street railway centers throughout the country. These figures cover for the most part the operation of the stations during the past year, and were obtained through the kindness of members of this Association, as well as from experience on the roads in Boston. The aggregate capacity of power stations represented is 98,387 KW., or 131,800 electrical HP.

The total cost of operation for the production of power alone from these stations during the past year has been $1,825,000, and *if* the power had been produced by all at as low a cost as it was in a number of the more economical stations the saving for the year would have amounted to $443,300. It is the chief purpose of this paper to explain the *if*, and to obtain some idea of its size.

In what has been published on this subject there are a great variety of opinions as to what should be included in the cost of power, and also as to whether the basis of comparison should be the car-mile or KW. hour, this latter being due to the fact that up to within a few years there had been no reliable instrument adopted by street railways for the measuring of their output.

The car-mile basis is not a fixed standard. A car-mile up hill takes a great deal of power, while a car-mile down hill should take none, and may be made a source of power.

In the analysis of costs of operation of power stations of various sizes and types it is first necessary to adopt a standard for the unit of power. We have seen that the car-mile is unreliable. Recording wattmeters are at present constructed which will measure the output in KW. hours. They can be made to give results which are accurate within a very few per cent. This statement is abundantly verified by actual experience, and is gradually becoming universally recognized. It is no doubt difficult for one who has been accustomed to figure cost of power production on a car-mile basis to reconcile himself to the KW. hour. It should, however, be very easy for the steam engineer who is accustomed to deal with HP., since the KW. hour equals 1.34 electrical HP. hours.

It was evidently the idea of your Executive Committee in limiting the title of this paper to cost at the switchboard to abolish the car mile and adopt the KW. hour as the unit of power. And in comparing the costs from the various stations I shall use this unit. For the benefit of those who are accustomed to considering the costs per car mile it will be interesting to know that on many roads a car mile takes just about 1 KW. hour. This is not true where grades and equipments are extremely heavy; in such cases two or three times this amount may be required.

In the costs of power, whether it is produced by steam or water, should be included the fixed charges as well as the cost of operation. Under fixed charges are interest, depreciation, insurance and taxes on the capital invested in the land, buildings and machinery of the power station. Under operating expenses are fuel, labor, supplies, repairs, superintendence and general expense. In both the fixed charges and operating expenses the component items vary between widely different limits, and it becomes impossible to construct a law that will predict the cost under all circumstances. On the other hand, for one who has had experience it is comparatively easy to predict what the power ought to cost under a given set of conditions. What it will cost must, of course, depend on management as well. In view of the

* Paper read at the Convention of the American Street Railway Association, Boston, Sept. 6-9, 1898.

variety of the circumstances governing these costs, I have deemed it advisable to establish for purposes of comparison a standard plant whose conditions are fixed.

It is not my intention to imply that the performance or equipment of this station which I shall employ as a standard is ideal or could not be bettered, but rather to assume equipment and performance based on facts obtained from stations in actual commercial operation during a long period of time. As this station is described, its performance may seem to border on the ideal, and there is no question but that its performance is consequent on favorable circumstances—very nearly, we may say, test conditions. It is, however, in my opinion, best to err on this side rather than on the other in establishing a station for comparison.

I shall assume the station to be located on the water front; the exact spot is unimportant, but since this Association has chosen Boston as its meeting place we can consistently locate the station here as well. I have fixed the capacity at 3,600 KW.; the building erected on firm ground requiring but little piling or filling, building and chimney of brick.

For equipment, three cross compound condensing engines, cylinders 28 in. and 56 in. by 5 ft. stroke, speed 80 revolutions per minute, steam pressure 150 lbs.; three 1,200-KW. direct-connected generators, six water-tube safety boilers, 500 HP. each, economizers and exhaust feed water heaters, electrically driven feed pumps and coal handling apparatus. Such a station would cost to install as follows:

CAPITAL INVESTED.

Building, foundations for engines and boilers, chimney, coal handling apparatus	$120,000
Engines and condensers, heaters, separators and piping	91,800
Feed pumps and economizers	18,000
Boilers and flue connections complete	61,000
Generators and switchboard complete	73,800
Land and docking facilities	17,000
Engineering and sundries	5,000
Total	$386,600

or about $107 per KW. capacity.

To obtain the figure for fixed charges I assume interest at 6 per cent., insurance and taxes 3 per cent., depreciation 2 per cent., total 11 per cent., which makes an annual fixed charge of $42,526.

I shall assume that this station produces 10,500,000 KW. hours per annum; dividing the annual charge by this figure gives four cents per KW. hour for fixed charges. The depreciation is not intended to cover repairs, which will be included under operating expenses. The 2 per cent. assumed for depreciation is to establish a sinking fund against the time when the station will have to be entirely replaced by one of more modern and economical design, time of replacement being taken at fifty years. A few years ago the time of replacement should have been assumed much shorter, owing to the imperfect design of power station apparatus then existing. But with the present advanced state of the art improvements cannot be expected to develop as rapidly.

Before arriving at the cost to produce power from this station it will be necessary to obtain the operating expenses. In making comparisons between stations of different sizes and types the cost of labor is the most perplexing item, some stations operating with two shifts, others three. Some have engineers paid at different rates, and men which appear on the records of some are in a capacity which in others is absent or replaced by men of another class and rate of pay. I therefore give the following method of analysis of the labor item, which gives satisfactory results when applied to station operation.

I can illustrate the method and at the same time derive the operating expenses by applying it to our standard station. It is assumed that this station operates with three shifts of men, the duration of each shift being eight hours. This makes the shift-hours per day 24, or 8,760 for the year. The same number of shift-hours would of course be obtained by two shifts of 12 hours each, as is the case with some stations. For the three-shift station, the first two probably would have the full complement of men, while the third would not, as the station might be shut down on that shift. But as there is considerable inspection, cleaning and overhauling, this shift requires almost as many men, though their rate of pay may be less. The highest rates of pay would be on the shift of heaviest load. The crew to operate the standard plant would be about as follows: Two engineers, one oiler, one helper, two firemen, one coal passer; total, seven men per shift.

The average rate of pay per man is taken at 27 cents per hour. This would be calculated from an actual station by dividing the total amount paid for wages, including chief engineer's salary, by the product of the number of men operating with the hours each has worked. The number of men per shift for this station being 7, I will divide this figure by 3.6, which is the figure expressing the capacity in 1,000 KW. units. This division gives 1.94 as the number of men per shift per 1,000 KW. capacity. This figure will vary with the type and size of station, as we shall see later. The fractional part of the man of course only appears in figuring.

Multiplying the 1.94 by the rate of pay, 27 cents, gives 52 cents as the cost of labor per hour per 1,000 KW. capacity. This multiplied by 3.6, the number of 1,000 KW. capacity, gives $1.87 as the total cost of labor required to operate the station per hour.

It will further aid in the analysis of the labor item to introduce the load factor. As this term is sometimes employed in a different sense from that used in this paper, I shall define it to be that per cent. which when multiplied by the capacity of the station in KW. and by the shift hours for the period gives the KW. hours' output for the time considered. I take as the load factor of this station 33 per cent. average for the year. You may remember that in the consideration of the fixed charges I gave as the KW. hours per year 10,500,000, which is 33.3 per cent. of 3,600 KW. multiplied by 8,760, the shift hours per annum.

It has been shown above that $1.87 is the average cost of labor to operate the station for one hour, and if we obtain the average KW. during the hour, which is KW. hours for that period, a simple division will give the figure for the cost of labor per KW. hour. The load factor gives the means of obtaining the KW. hours, and by multiplying 3.6 by 1,000 and 33.3 per cent. gives 12,000 as the average KW. for the hour or KW. hours for that period. Dividing $1.87, cost of labor to operate the station per hour, by 1,200 gives .157 cent as the cost of labor per KW. hour.

But 3.6, the figure representing the capacity, was used as a multiplier in obtaining both the cost of labor, $1.87, and 1,200 KW. hours. It therefore disappears in the division, and the expression for t cost of labor per KW. hour is made independent of the capacity of the station to that extent. The rule

then for obtaining the cost of labor per KW. hour for any station is to multiply the rate of pay of the men by the number of men per 1,000 KW. capacity and divide by the product of the load factor and 1,000.

The use of this method will be illustrated if we compare the cost of labor per KW. hour in the first two columns of Table No. 1. It is .157 for the standard and 56 cents for station No. 1. It is rather difficult to account for this great increase until we notice that the men per 1,000 KW. is 4.7 as against 1.94. The rate of pay and load factor also enter, as I shall show later.

I have constructed a diagram which gives the results of this expression for cost of labor for all usual rates of pay, load factors and men per 1,000 KW. This diagram is based on a rate of 27 cents per hour, and there is also given a reduction table, which gives the per cent. to be added or subtracted for other rates than this. To illustrate its use, suppose we have a station whose equipment requires five men per shift per 1,000 KW. capacity. During a month of high output it might operate at a 30 per cent. load factor. On the diagram, following 5 up to 30 gives cost of labor at 45 cents per KW. hour. In a lighter month the station might operate at a 15 per cent. load factor. Following 5 up to 15 gives 9 cents, or twice as much for labor per KW. hour.
